| 2 to 0                      | BC[2:0]                           | 000           | R/W | <p>Bit Counter</p> <p>These bits specify the number of bits to be transferred next. When read, the remaining number of transfer bits is indicated. With the I<sup>2</sup>C bus format, the data is transferred with one addition acknowledge bit. Should be made between transfer frames. If these bits are set to a value other than B'000, the setting should be made while the SCL pin is low. The value returns to B'000 at the end of a data transfer, including the acknowledge bit. In addition, the value automatically returns to B'111 after the detection of a stop condition. These bits are cleared by a power-on reset and in software standby mode and module standby mode. These bits are also cleared by setting the IICRST bit of ICCR2 to 1. With the clocked synchronous serial format, these bits should not be modified.</p> <table><tr><td>I<sup>2</sup>C Bus Format</td><td>Clocked Synchronous Serial Format</td></tr><tr><td>000: 9 bits</td><td>000: 8 bits</td></tr><tr><td>001: 2 bits</td><td>001: 1 bit</td></tr><tr><td>010: 3 bits</td><td>010: 2 bits</td></tr><tr><td>011: 4 bits</td><td>011: 3 bits</td></tr><tr><td>100: 5 bits</td><td>100: 4 bits</td></tr><tr><td>101: 6 bits</td><td>101: 5 bits</td></tr><tr><td>110: 7 bits</td><td>110: 6 bits</td></tr><tr><td>111: 8 bits</td><td>111: 7 bits</td></tr></table> | I <sup>2</sup> C Bus Format | Clocked Synchronous Serial Format | 000: 9 bits | 000: 8 bits | 001: 2 bits | 001: 1 bit | 010: 3 bits | 010: 2 bits | 011: 4 bits | 011: 3 bits | 100: 5 bits | 100: 4 bits | 101: 6 bits | 101: 5 bits | 110: 7 bits | 110: 6 bits | 111: 8 bits | 111: 7 bits |

### 17.3.4 I<sup>2</sup>C Bus Interrupt Enable Register (ICIER)

ICIER is an 8-bit readable/writable register that enables or disables interrupt sources and acknowledge bits, sets acknowledge bits to be transferred, and confirms acknowledge bits received.

### 17.3.5 I<sup>2</sup>C Bus Status Register (ICSR)

ICSR is an 8-bit readable/writable register that confirms interrupt request flags and their status.

### 17.3.6 Slave Address Register (SAR)

SAR is an 8-bit readable/writable register that selects the communications format and sets the slave address. In slave mode with the I<sup>2</sup>C bus format, if the upper seven bits of SAR match the upper seven bits of the first frame received after a start condition, this module operates as the slave device.

### 17.3.7 I<sup>2</sup>C Bus Transmit Data Register (ICDRT)

ICDRT is an 8-bit readable/writable register that stores the transmit data. When ICDRT detects the space in the shift register (ICDRS), it transfers the transmit data which is written in ICDRT to ICDRS and starts transferring data. If the next transfer data is written to ICDRT while transferring data of ICDRS, continuous transfer is possible.

|                |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|

### 17.3.8 I<sup>2</sup>C Bus Receive Data Register (ICDRR)

ICDRR is an 8-bit register that stores the receive data. When data of one byte is received, ICDRR transfers the receive data from ICDRS to ICDRR and the next data can be received. ICDRR is a receive-only register, therefore the CPU cannot write to this register.

|                |                      |                      |                      |                      |                      |                      |                      |                      |

### 17.3.9 I<sup>2</sup>C Bus Shift Register (ICDRS)

ICDRS is a register that is used to transfer/receive data. In transmission, data is transferred from ICDRT to ICDRS and the data is sent from the SDA pin. In reception, data is transferred from ICDRS to ICDRR after data of one byte is received. This register cannot be read directly from the CPU.

|                |                      |                      |                      |                      |                      |                      |                      |                      |

### 17.3.10 NF2CYC Register (NF2CYC)

NF2CYC is an 8-bit readable/writable register that selects the range of the noise filtering for the SCL and SDA pins. For details of the noise filter, see section 17.4.7, Noise Filter.

## 17.4 Operation

The I<sup>2</sup>C bus interface 3 can communicate either in I<sup>2</sup>C bus mode or clocked synchronous serial mode by setting FS in SAR.

### 17.4.1 I<sup>2</sup>C Bus Format

Figure 17.3 shows the I<sup>2</sup>C bus formats. Figure 17.4 shows the I<sup>2</sup>C bus timing. The first frame following a start condition always consists of eight bits.

**Figure 17.3 I<sup>2</sup>C Bus Formats**

**Figure 17.4 I<sup>2</sup>C Bus Timing**

#### [Legend]

S: Start condition. The master device drives SDA from high to low while SCL is high.

SLA: Slave address

R/W: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receive device drives SDA to low.

DATA: Transfer data

P: Stop condition. The master device drives SDA from low to high while SCL is high.

### 17.4.2 Master Transmit Operation

In master transmit mode, the master device outputs the transmit clock and transmit data, and the slave device returns an acknowledge signal. For master transmit mode operation timing, refer to figures 17.5 and 17.6. The transmission procedure and operations in master transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Also, set bits CKS[3:0] in ICCR1. (Initial setting)
2. Read the BBSY flag in ICCR2 to confirm that the bus is released. Set the MST and TRS bits in ICCR1 to select master transmit mode. Then, write 1 to BBSY and 0 to SCP. (Start condition issued) This generates the start condition.
3. After confirming that TDRE in ICSR has been set, write the transmit data (the first byte data show the slave address and  $R/\overline{W}$ ) to ICDRT. At this time, TDRE is automatically cleared to 0, and data is transferred from ICDRT to ICDRS. TDRE is set again.
4. When transmission of one byte data is completed while TDRE is 1, TEND in ICSR is set to 1 at the rise of the 9th transmit clock pulse. Read the ACKBR bit in ICIER, and confirm that the slave device has been selected. Then, write second byte data to ICDRT. When ACKBR is 1, the slave device has not been acknowledged, so issue the stop condition. To issue the stop condition, write 0 to BBSY and SCP. SCL is fixed low until the transmit data is prepared or the stop condition is issued.
5. The transmit data after the second byte is written to ICDRT every time TDRE is set.
6. Write the number of bytes to be transmitted to ICDRT. Wait until TEND is set (the end of last byte data transmission) while TDRE is 1, or wait for NACK (NACKF in ICSR = 1) from the receive device while ACKE in ICIER is 1. Then, issue the stop condition to clear TEND or NACKF.
7. When the STOP bit in ICSR is set to 1, the operation returns to the slave receive mode.

Figure 17.5 Master Transmit Mode Operation Timing (1)

Figure 17.6 Master Transmit Mode Operation Timing (2)

### 17.4.3 Master Receive Operation

In master receive mode, the master device outputs the receive clock, receives data from the slave device, and returns an acknowledge signal. For master receive mode operation timing, refer to figures 17.7 and 17.8. The reception procedure and operations in master receive mode are shown below.

1. Clear the TEND bit in ICSR to 0, then clear the TRS bit in ICCR1 to 0 to switch from master transmit mode to master receive mode. Then, clear the TDRE bit to 0.
2. When ICDRR is read (dummy data read), reception is started, and the receive clock is output, and data received, in synchronization with the internal clock. The master device outputs the level specified by ACKBT in ICIER to SDA, at the 9th receive clock pulse.
3. After the reception of first frame data is completed, the RDRF bit in ICSR is set to 1 at the rise of 9th receive clock pulse. At this time, the receive data is read by reading ICDRR, and RDRF is cleared to 0.
4. The continuous reception is performed by reading ICDRR every time RDRF is set. If 8th receive clock pulse falls after reading ICDRR by the other processing while RDRF is 1, SCL is fixed low until ICDRR is read.
5. If next frame is the last receive data, set the RCVD bit in ICCR1 to 1 before reading ICDRR. This enables the issuance of the stop condition after the next reception.
6. When the RDRF bit is set to 1 at rise of the 9th receive clock pulse, issue the stage condition.
7. When the STOP bit in ICSR is set to 1, read ICDRR. Then clear the RCVD bit to 0.
8. The operation returns to the slave receive mode.

**Note:** If only one byte is received, read ICDRR (dummy-read) after the RCVD bit in ICCR1 is set.

Figure 17.7 Master Receive Mode Operation Timing (1)

Figure 17.8 Master Receive Mode Operation Timing (2)

### 17.4.4 Slave Transmit Operation

In slave transmit mode, the slave device outputs the transmit data, while the master device outputs the receive clock and returns an acknowledge signal. For slave transmit mode operation timing, refer to figures 17.9 and 17.10.

The transmission procedure and operations in slave transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set bits CKS[3:0] in ICCR1. (Initial setting) Set the MST and TRS bits in ICCR1 to select slave receive mode, and wait until the slave address matches.
2. When the slave address matches in the first frame following detection of the start condition, the slave device outputs the level specified by ACKBT in ICIER to SDA, at the rise of the 9th clock pulse. At this time, if the 8th bit data (R/W) is 1, the TRS bit in ICCR1 and the TDRE bit in ICSR are set to 1, and the mode changes to slave transmit mode automatically. The continuous transmission is performed by writing transmit data to ICDRT every time TDRE is set.
3. If TDRE is set after writing last transmit data to ICDRT, wait until TEND in ICSR is set to 1, with TDRE = 1. When TEND is set, clear TEND.
4. Clear TRS for the end processing, and read ICDRR (dummy read). SCL is opened.
5. Clear TDRE.

**Figure 17.9 Slave Transmit Mode Operation Timing (1)**

### 17.4.5 Slave Receive Operation

In slave receive mode, the master device outputs the transmit clock and transmit data, and the slave device returns an acknowledge signal. For slave receive mode operation timing, refer to figures 17.11 and 17.12. The reception procedure and operations in slave receive mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set bits CKS[3:0] in ICCR1. (Initial setting) Set the MST and TRS bits in ICCR1 to select slave receive mode, and wait until the slave address matches.
2. When the slave address matches in the first frame following detection of the start condition, the slave device outputs the level specified by ACKBT in ICIER to SDA, at the rise of the 9th clock pulse. At the same time, RDRF in ICSR is set to read ICDRR (dummy read). (Since the read data show the slave address and R/W, it is not used.)
3. Read ICDRR every time RDRF is set. If 8th receive clock pulse falls while RDRF is 1, SCL is fixed low until ICDRR is read. The change of the acknowledge before reading ICDRR, to be returned to the master device, is reflected to the next transmit frame.
4. The last byte data is read by reading ICDRR.

**Figure 17.11 Slave Receive Mode Operation Timing (1)**

Figure 17.12 Slave Receive Mode Operation Timing (2)

17.4.6 Clocked Synchronous Serial Format

This module can be operated with the clocked synchronous serial format, by setting the FS bit in SAR to 1. When the MST bit in ICCR1 is 1, the transfer clock output from SCL is selected. When MST is 0, the external clock input is selected.

(1) Data Transfer Format

Figure 17.13 shows the clocked synchronous serial transfer format.

The transfer data is output from the fall to the fall of the SCL clock, and the data at the rising edge of the SCL clock is guaranteed. The MLS bit in ICMR sets the order of data transfer, in either the MSB first or LSB first. The output level of SDA can be changed during the transfer wait, by the SDAO bit in ICCR2.

Figure 17.13 Clocked Synchronous Serial Transfer Format

## (2) Transmit Operation

In transmit mode, transmit data is output from SDA, in synchronization with the fall of the transfer clock. The transfer clock is output when MST in ICCR1 is 1, and is input when MST is 0. For transmit mode operation timing, refer to figure 17.14. The transmission procedure and operations in transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set the MST and CKS[3:0] bits in ICCR1. (Initial setting)
2. Set the TRS bit in ICCR1 to select the transmit mode. Then, TDRE in ICSR is set.
3. Confirm that TDRE has been set. Then, write the transmit data to ICDRT. The data is transferred from ICDRT to ICDRS, and TDRE is set automatically. The continuous transmission is performed by writing data to ICDRT every time TDRE is set. When changing from transmit mode to receive mode, clear TRS while TDRE is 1.

**Figure 17.14 Transmit Mode Operation Timing**

### (3) Receive Operation

In receive mode, data is latched at the rise of the transfer clock. The transfer clock is output when MST in ICCR1 is 1, and is input when MST is 0. For receive mode operation timing, refer to figure 17.15. The reception procedure and operations in receive mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set bits CKS[3:0] in ICCR1. (Initial setting)
2. When the transfer clock is output, set MST to 1 to start outputting the receive clock.
3. When the receive operation is completed, data is transferred from ICDRS to ICDRR and RDRF in ICSR is set. When MST = 1, the next byte can be received, so the clock is continually output. The continuous reception is performed by reading ICDRR every time RDRF is set. When the 8th clock is risen while RDRF is 1, the overrun is detected and AL/OVE in ICSR is set. At this time, the previous reception data is retained in ICDRR.
4. To stop receiving when MST = 1, set RCVD in ICCR1 to 1, then read ICDRR. Then, SCL is fixed high after receiving the next byte data.

Notes: Follow the steps below to receive only one byte with MST = 1 specified. See figure 17.16 for the operation timing.

1. Set the ICE bit in ICCR1 to 1. Set bits CKS[3:0] in ICCR1. (Initial setting)
2. Set MST = 1 while the RCVD bit in ICCR1 is 0. This causes the receive clock to be output.
3. Check if the BC2 bit in ICMR is set to 1 and then set the RCVD bit in ICCR1 to 1. This causes the SCL to be fixed to the high level after outputting one byte of the receive clock.

Figure 17.15 Receive Mode Operation Timing

Figure 17.16 Operation Timing For Receiving One Byte (MST = 1)

### 17.4.7 Noise Filter

The logic levels at the SCL and SDA pins are routed through noise filters before being latched internally. Figure 17.17 shows a block diagram of the noise filter circuit.

The noise filter consists of three cascaded latches and a match detector. The SCL (or SDA) input signal is sampled on the peripheral clock. When NF2CYC is set to 0, this signal is not passed forward to the next circuit unless the outputs of both latches agree. When NF2CYC is set to 1, this signal is not passed forward to the next circuit unless the outputs of three latches agree. If they do not agree, the previous value is held.

**Figure 17.17 Block Diagram of Noise Filter**

### 17.4.8 Example of Use

Flowcharts in respective modes that use the I<sup>2</sup>C bus interface 3 are shown in figures 17.18 to 17.21.

Figure 17.18 Sample Flowchart for Master Transmit Mode

Figure 17.19 Sample Flowchart for Master Receive Mode

**Figure 17.20 Sample Flowchart for Slave Transmit Mode**

**Figure 17.21 Sample Flowchart for Slave Receive Mode**

## 17.5 Interrupt Requests

There are six interrupt requests in this module; transmit data empty, transmit end, receive data full, NACK detection, STOP recognition, and arbitration lost/overrun error. Table 17.4 shows the contents of each interrupt request.

**Table 17.4 Interrupt Requests**

| Interrupt Request                  | Abbreviation | Interrupt Condition        | I <sup>2</sup> C Bus Format | Clocked Synchronous Serial Format |
|------------------------------------|--------------|----------------------------|-----------------------------|-----------------------------------|
| Transmit data Empty                | TXI          | (TDRE = 1) • (TIE = 1)     | √                           | √                                 |
| Transmit end                       | TEI          | (TEND = 1) • (TEIE = 1)    | √                           | √                                 |
| Receive data full                  | RXI          | (RDRF = 1) • (RIE = 1)     | √                           | √                                 |
| STOP recognition                   | STPI         | (STOP = 1) • (STIE = 1)    | √                           | —                                 |
| NACK detection                     | NAKI         | {(NACKF = 1) + (AL = 1)} • | √                           | —                                 |
| Arbitration lost/<br>overrun error |              | (NAKIE = 1)                | √                           | √                                 |

When the interrupt condition described in table 17.4 is 1, the CPU executes an interrupt exception handling. Note that a TXI or RXI interrupt can activate the DMAC if the setting for DMAC activation has been made. In such a case, an interrupt request is not sent to the CPU. Interrupt sources should be cleared in the exception handling. The TDRE and TEND bits are automatically cleared to 0 by writing the transmit data to ICDRT. The RDRF bit is automatically cleared to 0 by reading ICDRR. The TDRE bit is set to 1 again at the same time when the transmit data is written to ICDRT. Therefore, when the TDRE bit is cleared to 0, then an excessive data of one byte may be transmitted.

## 17.6 Bit Synchronous Circuit

In master mode, this module has a possibility that high level period may be short in the two states described below.

- When SCL is driven to low by the slave device
- When the rising speed of SCL is lowered by the load of the SCL line (load capacitance or pull-up resistance)

Therefore, it monitors SCL and communicates by bit with synchronization.

Figure 17.22 shows the timing of the bit synchronous circuit and table 17.5 shows the time when the SCL output changes from low to Hi-Z then SCL is monitored.

(a) SCL is normally driven

(b) When SCL is driven to low by the slave device

(c) When the rising speed of SCL is lowered

- Notes: 1. The clock is the transfer rate clock set by the CKS[3:0] bits in the I<sup>2</sup>C bus control register 1 (ICCR1).  
 2. When the NF2CYC bit in NF2CYC (NF2CYC) is set to 0, the internal delay time is 3 to 4  $t_{pccy}$ .  
 When this bit is set to 1, the internal delay time is 4 to 5  $t_{pccy}$ .

**Figure 17.22 Bit Synchronous Circuit Timing**

**Table 17.5 Time for Monitoring SCL**

| CKS3 | CKS2 | Time for Monitoring SCL |
|------|------|-------------------------|
| 0    | 0    | 9 tpcyc                 |
|      | 1    | 21 tpcyc                |
| 1    | 0    | 39 tpcyc                |
|      | 1    | 87 tpcyc                |

Note: tpcyc =  $P\phi \times \text{cyc}$

## 17.7 Usage Notes

### 17.7.1 Note on the Setting of ICCR1.CKS[3:0]

The bit field ICCR1.CKS[3:0] should not be H'7 or H'F at the same time as NF2CYC.PRS = 1.

### 17.7.2 Settings for Multi-Master Operation

In multi-master operation, when the setting for IIC transfer rate (ICCR1.CKS[3:0]) makes this LSI slower than the other masters, pulse cycles with an unexpected length will infrequently be output on SCL.

Be sure to specify a transfer rate that is at least 1/1.8 of the fastest transfer rate among the other masters.

### 17.7.3 Note on Master Receive Mode

Reading ICDRR around the falling edge of the 8th clock might fail to fetch the receive data.

In addition, when RCVD is set to 1 around the falling edge of the 8th clock and the receive buffer is full, a stop condition may not be issued.

Use either 1 or 2 below as a measure against the situations above.

1. In master receive mode, read ICDRR before the rising edge of the 8th clock.
2. In master receive mode, set the RCVD bit to 1 so that transfer proceeds in byte units.

#### 17.7.4 Note on Setting ACKBT in Master Receive Mode

In master receive mode operation, set ACKBT before the falling edge of the 8th SCL cycle of the last data being continuously transferred. Not doing so can lead to an overrun for the slave transmission device.

#### 17.7.5 Note on the States of Bits MST and TRN when Arbitration Is Lost

When sequential bit-manipulation instructions are used to set the MST and TRS bits to select master transmission in multi-master operation, a conflicting situation where AL in ICSR = 1 but the mode is master transmit mode (MST = 1 and TRS = 1) may arise; this depends on the timing of the loss of arbitration when the bit manipulation instruction for TRS is executed.

This can be avoided in either of the following ways.

- In multi-master operation, use the MOV instruction to set the MST and TRS bits.
- When arbitration is lost, check whether the MST and TRS bits are 0. If the MST and TRS bits have been set to a value other than 0, clear the bits to 0

#### 17.7.6 Note on I2C-bus Interface Master Receive Mode

After a master receive operation is completed, confirm the falling edge of the ninth clock cycle of the SCL signal and generate a stop condition or regenerate a start condition.

#### 17.7.7 Note on IICRST and BBSY Bits

When 1 is written to IICRST in ICCR2, this LSI release SCL and SDA pins. Then, if the SDA level changes from low to high under the condition of SCL = high, BBSY in ICCR2 is cleared to 0 assuming that the stop condition has been issued.

#### 17.7.8 Note on Issuance of Stop Conditions in Master Transmit Mode while ACKE = 1

When a stop condition is issued in master transmit mode while the ACKE bit in the I<sup>2</sup>C bus interrupt enable register (ICIER) is 1, the stop condition may not be normally output depending on the issued timing. To avoid this, recognize the falling edge of the ninth clock before issuance of the stop condition.

The falling edge of the ninth clock can be recognized by checking the SCLO bit in the I<sup>2</sup>C control register 2 (ICCR2).

## Section 18 Serial Sound Interface (SSI)

The serial sound interface (SSI) is a module designed to send or receive audio data interface with various devices offering I<sup>2</sup>S bus compatibility. It also provides additional modes for other common formats, as well as support for multi-channel mode.

### 18.1 Features

- Number of channels: Four channels
- Operating mode: Non-compressed mode  
The non-compressed mode supports serial audio streams divided by channels.
- Serves as both a transmitter and a receiver
- Capable of using serial bus format
- Asynchronous transfer takes place between the data buffer and the shift register.
- It is possible to select a value as the dividing ratio for the clock used by the serial bus interface.
- It is possible to control data transmission or reception with DMAC and interrupt requests.
- Selects the oversampling clock input from among the following pins:  
EXTAL, XTAL (Clock operation modes 0 and 1: 10 MHz to 33.33 MHz)  
CKIO (Clock operation mode 2: 40 MHz to 50 MHz\*)  
AUDIO\_CLK (1 MHz to 40 MHz)  
AUDIO\_X1, AUDIO\_X2 (crystal resonator connected: 10 MHz to 40 MHz;  
external clock input: 1 MHz to 40 MHz)

Note: \* Do not select CKIO as the source for the oversampling clock when using a CKIO frequency exceeding 50 MHz in clock operation mode 2.

Figure 18.1 shows a schematic diagram of the four channels in the SSI module.

**Figure 18.1 Schematic Diagram of SSI Module**

Figure 18.2 shows a block diagram of the SSI module.

**Figure 18.2 Block Diagram of SSI**

## 18.2 Input/Output Pins

Table 18.1 shows the pin assignments relating to the SSI module.

**Table 18.1 Pin Assignments**

| Pin Name  | Number of Pins | I/O    | Description                                                |
|-----------|----------------|--------|------------------------------------------------------------|
| SSISCK0   | 1              | I/O    | Serial bit clock                                           |
| SSIWS0    | 1              | I/O    | Word selection                                             |
| SSIDATA0  | 1              | I/O    | Serial data input/output                                   |
| SSISCK1   | 1              | I/O    | Serial bit clock                                           |
| SSIWS1    | 1              | I/O    | Word selection                                             |
| SSIDATA1  | 1              | I/O    | Serial data input/output                                   |
| SSISCK2   | 1              | I/O    | Serial bit clock                                           |
| SSIWS2    | 1              | I/O    | Word selection                                             |
| SSIDATA2  | 1              | I/O    | Serial data input/output                                   |
| SSISCK3   | 1              | I/O    | Serial bit clock                                           |
| SSIWS3    | 1              | I/O    | Word selection                                             |
| SSIDATA3  | 1              | I/O    | Serial data input/output                                   |
| AUDIO_CLK | 1              | Input  | External clock for audio (entering oversampling clock)     |
| AUDIO_X1  | 1              | Input  | Crystal oscillator for audio (entering oversampling clock) |
| AUDIO_X2  | 1              | Output |                                                            |

## 18.3 Register Description

The SSI has the following registers. Note that explanation in the text does not refer to the channels.

**Table 18.2 Register Description**

| Channel | Register Name            | Abbrevia-<br>tion | R/W  | Initial Value | Address    | Access<br>Size |
|---------|--------------------------|-------------------|------|---------------|------------|----------------|
| 0       | Control register 0       | SSICR_0           | R/W  | H'00000000    | H'FFFFC000 | 32             |
|         | Status register 0        | SSISR_0           | R/W* | H'02000003    | H'FFFFC004 | 32             |
|         | Transmit data register 0 | SSITDR_0          | R/W  | H'00000000    | H'FFFFC008 | 32             |
|         | Receive data register 0  | SSIRDR_0          | R    | H'00000000    | H'FFFFC00C | 32             |
| 1       | Control register 1       | SSICR_1           | R/W  | H'00000000    | H'FFFFC800 | 32             |
|         | Status register 1        | SSISR_1           | R/W* | H'02000003    | H'FFFFC804 | 32             |
|         | Transmit data register 1 | SSITDR_1          | R/W  | H'00000000    | H'FFFFC808 | 32             |
|         | Receive data register 1  | SSIRDR_1          | R    | H'00000000    | H'FFFFC80C | 32             |
| 2       | Control register 2       | SSICR_2           | R/W  | H'00000000    | H'FFFFD000 | 32             |
|         | Status register 2        | SSISR_2           | R/W* | H'02000003    | H'FFFFD004 | 32             |
|         | Transmit data register 2 | SSITDR_2          | R/W  | H'00000000    | H'FFFFD008 | 32             |
|         | Receive data register 2  | SSIRDR_2          | R    | H'00000000    | H'FFFFD00C | 32             |
| 3       | Control register 3       | SSICR_3           | R/W  | H'00000000    | H'FFFFD800 | 32             |
|         | Status register 3        | SSISR_3           | R/W* | H'02000003    | H'FFFFD804 | 32             |
|         | Transmit data register 3 | SSITDR_3          | R/W  | H'00000000    | H'FFFFD808 | 32             |
|         | Receive data register 3  | SSIRDR_3          | R    | H'00000000    | H'FFFFD80C | 32             |

Note: \* Although bits 26 and 27 in this register can be read from or written to, bits other than these are read-only. For details, refer to section 18.3.2, Status Register (SSISR).

### 18.3.1 Control Register (SSICR)

SSICR is a readable/writable 32-bit register that controls the IRQ, selects the polarity status, and sets operating mode.

### 18.3.2 Status Register (SSISR)

SSISR consists of status flags indicating the operational status of the SSI module and bits indicating the current channel numbers and word numbers.

This can lead to the same received sample being stored twice by the host leading to potential corruption of multi-channel data.</li> <li>• TRMD = 1 (Transmit mode)<br/>If UIRQ = 1, SSITDR did not have data written to it before it was required for transmission. This will lead to the same sample being transmitted once more and a potential corruption of multi-channel data. This is more serious error than a receive mode underflow as the output SSI data results in error.</li> </ul> <p>Note: When underflow error occurs, the current data in the data buffer of this module is transmitted until the next data is filled.</p> |

Note: \* The bit can be read or written to. Writing 0 initializes the bit, but writing 1 is ignored.

### 18.3.3 Transmit Data Register (SSITDR)

SSITDR is a 32-bit register that stores data to be transmitted.

Data written to this register is transferred to the shift register upon transmission request. If the data word length is less than 32 bits, the alignment is determined by the setting of the PDTA control bit in SSICR. The data in the buffer can be accessed by reading this register.

### 18.3.4 Receive Data Register (SSIRDR)

SSIRDR is a 32-bit register that stores receive messages.

Data in this register is transferred from the shift register each time data word is received. If the data word length is less than 32 bits, the alignment is determined by the setting of the PDTA control bit in SSICR.

## 18.4 Operation Description

### 18.4.1 Bus Format

The SSI module can operate as a transmitter or a receiver and can be configured into many serial bus formats in either mode.

The bus format can be selected from one of the four major modes shown in table 18.3.

**Table 18.3 Bus Format for SSI Module**

|            | Non-Compressed<br>Slave Receiver | Non-Compressed<br>Slave Transmitter | Non-Compressed<br>Master Receiver | Non-Compressed<br>Master Transmitter |
|------------|----------------------------------|-------------------------------------|-----------------------------------|--------------------------------------|

### 18.4.2 Non-Compressed Modes

The non-compressed modes support all serial audio streams split into channels. It supports the I<sup>2</sup>S compatible format as well as many more variants on these modes.

#### (1) Slave Receiver

This mode allows the module to receive serial data from another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of the SSI module, operation is not guaranteed.

#### (2) Slave Transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of the SSI module, operation is not guaranteed.

#### (3) Master Receiver

This mode allows the module to receive serial data from another device. The clock and word select signals are internally derived from the oversampling clock. The format of these signals is defined in the configuration fields of the SSI module. If the incoming data does not follow the configured format, operation is not guaranteed.

#### (4) Master Transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signals are internally derived from the oversampling clock. The format of these signals is defined in the configuration fields of the SSI module.

#### (5) Operating Setting Related to Word Length

All bits related to the SSICR's word length are valid in non-compressed modes. There are many configurations the SSI module supports, but some of the combinations are shown below for the I<sup>2</sup>S compatible format, MSB-first and left-aligned format, and MSB-first and right-aligned format.

- I<sup>2</sup>S Compatible Format

Figures 18.3 and 18.4 demonstrate the supported the I<sup>2</sup>S compatible format both without and with padding. Padding occurs when the data word length is smaller than the system word length.

**Figure 18.3 I<sup>2</sup>S Compatible Format (without Padding)**

**Figure 18.4 I<sup>2</sup>S Compatible Format (with Padding)**

Figure 18.5 shows the MSB-first and left-aligned format and figure 18.6 shows the MSB-first and right-aligned format. Padding is assumed in both cases, but may not be present in a final implementation if the system word length equals the data word length.

- MSB-first and Left-Aligned Format

**Figure 18.5 MSB-first and Left-Aligned Format**  
(Transmitted and received in the order of serial data and padding bits)

- MSB-first and Right-Aligned Format

**Figure 18.6 MSB-first and Right-Aligned Format**  
(Transmitted and received in the order of padding bits and serial data)

## (6) Multi-channel Formats

Some devices extend the definition of the specification by I<sup>2</sup>S bus and allow more than 2 channels to be transferred within two system words.

The SSI module supports the transfer of 4, 6 and 8 channels by using the CHNL, SWL and DWL bits only when the system word length (SWL) is greater than or equal to the data word length (DWL) multiplied by channels (CHNL).

Table 18.4 shows the number of padding bits for each of the valid setting. If setting is not valid, “—” is indicated instead of a number.

**Table 18.4 The Number of Padding Bits for Each Valid Setting**

| Decoded Channels per System Word |                                  | DWL[2:0]  |                     |     |     |     |     |     |     |     |
|----------------------------------|----------------------------------|-----------|---------------------|-----|-----|-----|-----|-----|-----|-----|
| Per System Word                  |                                  | 000       | 001                 | 010 | 011 | 100 | 101 | 110 |     |     |
| CHNL [1:0]                       | Decoded Channels per System Word | SWL [2:0] | Decoded Word Length | 8   | 16  | 18  | 20  | 22  | 24  | 32  |
| 00                               | 1                                | 000       | 8                   | 0   | —   | —   | —   | —   | —   | —   |

When the SSI module acts as a transmitter, each word written to SSITDR is transmitted to the serial audio bus in the order they are written. When the SSI module acts as a receiver, each word received by the serial audio bus is read in the order received from the SSIRDR register.

Figures 18.7 to 18.9 show how 4, 6 and 8 channels are transferred to the serial audio bus. Note that there are no padding bits in the first example, the second example is left-aligned and the third is right-aligned. This selection is arbitrary and is just for demonstration purposes only.

**Figure 18.7 Multi-Channel Format (4 Channels Without Padding)**

**Figure 18.8 Multi-Channel Format (6 Channels with High Padding)**

**Figure 18.9 Multi-Channel Format (8 channels; transmitted and received in the order of padding bits and serial data; with padding)**

**(7) Bit Setting Configuration Format**

Several more configuration bits in non-compressed mode are shown below. These bits are not mutually exclusive, but some combinations may not be useful for any other device.

These configuration bits are described below with reference to figure 18.10.

**Figure 18.10 Basic Sample Format  
(Transmit Mode with Example System/Data Word Length)**

Figure 18.10 uses a system word length of 6 bits and a data word length of 4 bits. These settings are not possible with the SSI module but are used only for clarification of the other configuration bits.

### 18.4.3 Operation Modes

There are three modes of operation: configuration, enabled and disabled. Figure 18.19 shows how the module enters each of these modes.

**Figure 18.19 Operation Modes**

#### (1) Configuration Mode

This mode is entered after the module is released from reset. All required configuration fields in the control register should be defined in this mode, before the SSI module is enabled by setting the EN bit.

Setting the EN bit causes the module to enter the module enabled mode.

#### (2) Module Enabled Mode

Operation of the module in this mode is dependent on the operation mode selected. For details, refer to section 18.4.4, Transmit Operation and section 18.4.5, Receive Operation, below.

#### 18.4.4 Transmit Operation

Transmission can be controlled either by DMA or interrupt.

DMA control is preferred to reduce the processor load. In DMA control mode the processor will only receive interrupts if there is an underflow or overflow of data or the DMAC has finished its transfer.

The alternative method is using the interrupts that the SSI module generates to supply data as required. This mode has a higher interrupt load as the module is only double buffered and will require data to be written at least every system word period.

When disabling the module, the SSI clock\* must remain present until the SSI module is in idle state, indicated by the IIRQ bit.

Figure 18.20 shows the transmit operation in DMA control mode, and figure 18.21 shows the transmit operation in interrupt control mode.

Note: \* Input clock from the SSISCK pin when SCKD = 0.  
Oversampling clock when SCKD = 1.

**(1) Transmission Using DMA Controller****Figure 18.20 Transmission Using DMA Controller**

## (2) Transmission Using Interrupt Data Flow Control

Figure 18.21 Transmission Using Interrupt Data Flow Control

### 18.4.5 Receive Operation

Like transmission, reception can be controlled either by DMA or interrupt.

Figures 18.22 and 18.23 show the flow of operation.

When disabling the SSI module, the SSI clock\* must be kept supplied until the IIRQ bit is in idle state.

Note: \* Input clock from the SSISCK pin when SCKD = 0.  
Oversampling clock when SCKD = 1.

**(1) Reception Using DMA Controller**

Note: \* If the SSI encounters an error interrupt underflow/overflow, go back to the start in the flowchart again.

**Figure 18.22 Reception Using DMA Controller**

**(2) Reception Using Interrupt Data Flow Control****Figure 18.23 Reception Using Interrupt Data Flow Control**

When an underflow or overflow error condition has matched, the CHNO [1:0] bit and the SWNO bit can be used to recover the SSI module to a known status. When an underflow or overflow occurs, the host can read the channel number and system word number to determine what point the serial audio stream has reached. In the transmitter case, the host can skip forward through the data it wants to transmit until it finds the sample data that matches what the SSI module is expecting to transmit next, and so resynchronize with the audio data stream. In the receiver case the host CPU can store null data to make the number of receive data items consistent until it is ready to store the sample data that the SSI module is indicating will be received next, and so resynchronize with the audio data stream.

#### 18.4.6 Temporary Stop and Restart Procedures in Transmit Mode

The following procedures can be used for implementation.

##### (1) Procedure for the transfer and stop without having to reconfigure the DMAC

1. Set SSICR.DMEN = 0 (disabling a DMA request) to stop the DMA transfer.
2. Wait for SSISR.DIRQ = 1 (transmit mode: the transmit buffer is empty) using a polling, interrupt, or the like.
3. With SSICR.EN = 0 (disabling an SSI module operation), stop the transfer.
4. Before attempting another transfer, make sure that SSISR.IDST = 1 is reached.
5. Set SSICR.EN = 1 (enabling an SSI module operation).
6. Wait for SSISR.DIRQ = 1, using a polling, interrupt, or the like.
7. Setting SSICR.DMEN = 1 (enabling a DMA request) will restart the DMA transfer.

##### (2) Procedure for Reconfiguring the DMAC after an SSI stop

1. Set SSICR.DMEN = 0 (disabling a DMA request) to stop the DMA transfer.
2. Wait for SSISR.DIRQ = 1 (transmit mode: the transmit buffer is empty), using a polling, interrupt, or the like.
3. With SSICR.EN = 0 (disabling an SSI module operation), stop the transfer.
4. Stop the DMAC with CHCR of the DMAC.
5. Before attempting another transfer, make sure that SSISR.IDST = 1 is reached.
6. Set SSICR.EN = 1 (enabling an SSI module operation).
7. Set the DMAC registers and start the transfer.
8. Setting SSICR.DMEN = 1 (enabling a DMA request) will restart the DMA transfer.

### 18.4.7 Serial Bit Clock Control

This function is used to control and select which clock is used for the serial bus interface.

If the serial clock direction is set to input ( $SCKD = 0$ ), the SSI module is in clock slave mode and the shift register uses the bit clock that was input to the SSISCK pin.

If the serial clock direction is set to output ( $SCKD = 1$ ), the SSI module is in clock master mode, and the shift register uses the oversampling clock, or the bit clock that is generated by dividing it. The oversampling clock is then divided by the ratio in the serial oversampling clock divide ratio bit ( $CKDV$ ) in SSICR and used as the bit clock in the shift register.

In either case the module pin, SSISCK, is the same as the bit clock.

## 18.5 Usage Notes

### 18.5.1 Limitations from Underflow or Overflow during DMA Operation

If an underflow or overflow occurs while the DMA is in operation, the module should be restarted. The transmit and receive buffers in the SSI consists of 32-bit registers that share the L and R channels. Therefore, data to be transmitted and received at the L channel may sometimes be transmitted and received at the R channel if an underflow or overflow occurs, for example, under the following condition: the control register (SSICR) has a 32-bit setting for both data word length (DWL2 to DWL0) and system word length (SWL2 to SWL0).

If an error occurrence is confirmed with two types of error interrupts (underflow, overflow) or the corresponding error status flag (the bits UIRQ, OIRQ in SSISR), write 0 to the EN and DMEN bit in SSICR to disable DMA transfer requests in this module, thus stopping the operation. (In this case, the direct memory access controller setting should also be stopped.) After this, write 0 to the error status flag bit to clear the error status, set the direct memory access controller again and restart the transfer.

## Section 19 Controller Area Network (RCAN-TL1)

### 19.1 Summary

#### 19.1.1 Overview

This document primarily describes the programming interface for the RCAN-TL1 (Renesas CAN Time Trigger Level 1) module. It serves to facilitate the hardware/software interface so that engineers involved in the RCAN-TL1 implementation can ensure the design is successful.

#### 19.1.2 Scope

The CAN Data Link Controller function is not described in this document. It is the responsibility of the reader to investigate the CAN Specification Document (see references). The interfaces from the CAN Controller are described, in so far as they pertain to the connection with the User Interface.

The programming model is described in some detail. It is not the intention of this document to describe the implementation of the programming interface, but to simply present the interface to the underlying CAN functionality.

The document places no constraints upon the implementation of the RCAN-TL1 module in terms of process, packaging or power supply criteria. These issues are resolved where appropriate in implementation specifications.

#### 19.1.3 Audience

In particular this document provides the design reference for software authors who are responsible for creating a CAN application using this module.

In the creation of the RCAN-TL1 user interface LSI engineers must use this document to understand the hardware requirements.

## 5. Road vehicles - Controller area network (CAN): Part 4: Time triggered communication (ISO-11898-4, 2004)

### 19.1.5 Features

- Supports CAN specification 2.0B
- Bit timing compliant with ISO-11898-1
- 32 Mailbox version
- Clock 16 to 33 MHz
- 31 programmable Mailboxes for transmit / receive + 1 receive-only mailbox
- Sleep mode for low power consumption and automatic recovery from sleep mode by detecting CAN bus activity
- Programmable receive filter mask (standard and extended identifier) supported by all Mailboxes
- Programmable CAN data rate up to 1MBit/s
- Transmit message queuing with internal priority sorting mechanism against the problem of priority inversion for real-time applications
- Data buffer access without SW handshake requirement in reception
- Flexible micro-controller interface
- Flexible interrupt structure
- 16-bit free running timer with flexible clock sources and pre-scaler, 3 Timer Compare Match Registers
- 6-bit Basic Cycle Counter for Time Trigger Transmission
- Timer Compare Match Registers with interrupt generation
- Timer counter clear / set capability
- Registers for Time-Trigger: Local\_Time, Cycle\_time, Ref\_Mark, Tx\_Enable Window, Ref\_Trigger\_Offset
- Flexible TimeStamp at SOF for both transmission and reception supported
- Time-Trigger Transmission, Periodic Transmission supported (on top of Event Trigger Transmission)
- Basic Cycle value can be embedded into a CAN frame and transmitted

## 19.2 Architecture

The RCAN-TL1 device offers a flexible and sophisticated way to organise and control CAN frames, providing the compliance to CAN2.0B Active and ISO-11898-1. The module is formed from 5 different functional entities. These are the Micro Processor Interface (MPI), Mailbox, Mailbox Control, Timer, and CAN Interface. The figure below shows the block diagram of the RCAN-TL1 Module. The bus interface timing is designed according to the peripheral bus I/F required for each product.

Figure 19.1 RCAN-TL1 architecture

- **Micro Processor Interface (MPI)**

The MPI allows communication between the Renesas CPU and the RCAN-TL1's registers/mailboxes to control the memory interface. It also contains the Wakeup Control logic that detects the CAN bus activities and notifies the MPI and the other parts of RCAN-TL1 so that the RCAN-TL1 can automatically exit the Sleep mode.

It contains registers such as MCR, IRR, GSR and IMR.

- **Mailbox**

The Mailboxes consists of RAM configured as message buffers and registers. There are 32 Mailboxes, and each mailbox has the following information.

<RAM>

- CAN message control (identifier, rtr, ide, etc)
- CAN message data (for CAN Data frames)
- Local Acceptance Filter Mask for reception

<Registers>

- CAN message control (dlc)
- Time Stamp for message reception/transmission
- 3-bit wide Mailbox Configuration, Disable Automatic Re-Transmission bit, Auto-Transmission for Remote Request bit, New Message Control bit
- Tx-Trigger Time

- **Mailbox Control**

The Mailbox Control handles the following functions.

- For received messages, compare the IDs and generate appropriate RAM addresses/data to store messages from the CAN Interface into the Mailbox and set/clear appropriate registers accordingly.
- To transmit event-triggered messages, run the internal arbitration to pick the correct priority message, and load the message from the Mailbox into the Tx-buffer of the CAN Interface and set/clear appropriate registers accordingly. In the case of time-triggered transmission, compare match of Tx-Trigger time invoke loading the messages.
- Arbitrates Mailbox accesses between the CPU and the Mailbox Control.
- Contains registers such as TXPR, TXCR, TXACK, ABACK, RXPR, RFPR, UMSR and MBIMR.

- **Timer**

The Timer function is the functional entity, which provides RCAN-TL1 with support for transmitting messages at a specific time frame and recording the result.

The Timer is a 16-bit free running up counter which can be controlled by the CPU. It provides one 16-bit Compare Match Register to compare with Local Time and two 16-bit ones to compare with Cycle Time. The Compare Match Registers can generate interrupt signals and clear the Counter.

The clock period of this Timer offers a wide selection derived from the system clock or can be programmed to be incremented with one nominal bit timing of CAN Bus.

Contains registers such as TCNTR, TTCR0, CMAX\_TEW, RFTROFF, TSR, CCR, CYCTR, RFMK, TCMR0, TCMR1, TCMR2 and TTTSEL.

- CAN Interface

This block conforms to the requirements for a CAN Bus Data Link Controller which is specified in Ref. [2, 4]. It fulfils all the functions of a standard DLC as specified by the OSI 7 Layer Reference model. This functional entity also provides the registers and the logic which are specific to a given CAN bus, which includes the Receive Error Counter, Transmit Error Counter, the Bit Configuration Registers and various useful Test Modes. This block also contains functional entities to hold the data received and the data to be transmitted for the CAN Data Link Controller.

## 19.3 Programming Model - Overview

The purpose of this programming interface is to allow convenient, effective access to the CAN bus for efficient message transfer. Please bear in mind that the user manual reports all settings allowed by the RCAN-TL1 IP. Different use of RCAN-TL1 is not allowed.

### 19.3.1 Memory Map

The diagram of the memory map is shown below.

|       | Bit 15                                             | Bit 0                       |       |                                               |   |
|-------|----------------------------------------------------|-----------------------------|-------|-----------------------------------------------|---|
| H'000 | Master Control Register (MCR)                      |                             | H'0A0 | Timer Compare Match Register 2 (TCMR2)        |   |
| H'002 | General Status Register(GSR)                       |                             |       |                                               |   |
| H'004 | Bit Configuration Register 1 (BCR1)                |                             | H'0A4 | Tx-Trigger Time Selection Register (TTTSEL)   |   |
| H'006 | Bit Configuration Register 0 (BCR0)                |                             |       |                                               |   |
| H'008 | Interrupt Request Register (IRR)                   |                             |       |                                               |   |
| H'00A | Interrupt Mask Register (IMR)                      |                             |       |                                               |   |
| H'00C | Transmit Error Counter (TEC)                       | Receive Error Counter (REC) |       |                                               |   |
|       |                                                    |                             | H'100 | Mailbox-0 Control 0 (StdID, ExtID, Rtr, Ide)  |   |
| H'020 | Transmit Pending Register (TXPR1)                  |                             | H'104 | LAFM                                          |   |
| H'022 | Transmit Pending Register (TXPR0)                  |                             |       |                                               |   |
|       |                                                    |                             | H'108 | 0                                             | 1 |
| H'028 | Transmit Cancel Register (TXCR1)                   |                             | H'10A | 2                                             | 3 |
| H'02A | Transmit Cancel Register (TXCR0)                   |                             | H'10C | 4                                             | 5 |
|       |                                                    |                             | H'10E | 6                                             | 7 |
| H'030 | Transmit Acknowledge Register (TXACK1)             |                             | H'110 | Mailbox-0 Control 1 (NMC, MBC, DLC) Timestamp |   |
| H'032 | Transmit Acknowledge Register (TXACK0)             |                             |       |                                               |   |
|       |                                                    |                             | H'120 | Mailbox-1 Control/LAFM/Data etc.              |   |
| H'038 | Abort Acknowledge Register (ABACK1)                |                             |       |                                               |   |
| H'03A | Abort Acknowledge Register (ABACK0)                |                             | H'140 | Mailbox-2 Control/LAFM/Data etc.              |   |
|       |                                                    |                             |       |                                               |   |
| H'040 | Receive Pending Register (RXPR1)                   |                             | H'160 | Mailbox-3 Control/LAFM/Data etc.              |   |
| H'042 | Receive Pending Register (RXPR0)                   |                             |       |                                               |   |
|       |                                                    |                             |       |                                               |   |

The locations not used (between H'000 and H'4F3) are reserved and cannot be accessed.

### 19.3.2 Mailbox Structure

Mailboxes play a role as message buffers to transmit/receive CAN frames. Each Mailbox is comprised of 3 identical storage fields that are 1): Message Control, 2): Local Acceptance Filter Mask, 3): Message Data. In addition some Mailboxes contain the following extra Fields: 4): Time Stamp, 5): Time Trigger configuration and 6): Time Trigger Control. The following table shows the address map for the control, LAFM, data, timestamp, Transmission Trigger Time and Time Trigger Control addresses for each mailbox.

| Mailbox             | Address   |           |           |           |            |              |            |
|---------------------|-----------|-----------|-----------|-----------|------------|--------------|------------|
|                     | Control0  | LAFM      | Data      | Control1  | Time Stamp | Trigger Time | TT control |
|                     | 4 bytes   | 4 bytes   | 8 bytes   | 2 bytes   | 2 bytes    | 2 bytes      | 2 bytes    |
| 0<br>(Receive Only) | 100 – 103 | 104 – 107 | 108 – 10F | 110 – 111 | 112 – 113  | No           | No         |
| 1                   | 120 – 123 | 124 – 127 | 128 – 12F | 130 – 131 | 132 – 133  | No           | No         |
| 2                   | 140 – 143 | 144 – 147 | 148 – 14F | 150 – 151 | 152 – 153  | No           | No         |
| 3                   | 160 – 163 | 164 – 167 | 168 – 16F | 170 – 171 | 172 – 173  | No           | No         |
| 4                   | 180 – 183 | 184 – 187 | 188 – 18F | 190 – 191 | 192 – 193  | No           | No         |

Mailbox-0 is a receive-only box, and all the other Mailboxes can operate as both receive and transmit boxes, dependant upon the MBC (Mailbox Configuration) bits in the Message Control. The following diagram shows the structure of a Mailbox in detail.

**Table 19.1 Roles of Mailboxes**

|           | Event Trigger |    | Time Trigger                                    |                              | Remark    |                 |
|-----------|---------------|----|-------------------------------------------------|------------------------------|-----------|-----------------|
|           | Tx            | Rx | Tx                                              | Rx                           | TimeStamp | Tx-Trigger Time |
| MB31      | OK            | OK | —                                               | time reference reception     | available | —               |
| MB30      | OK            | OK | time reference transmission in time master mode | reception in time slave mode | available | available       |
| MB29 - 24 | OK            | OK | OK                                              | OK                           | —         | available       |
| MB23 - 16 | OK            | OK | — (ET)                                          | OK                           | —         | —               |
| MB15 - 1  | OK            | OK | — (ET)                                          | OK                           | available | —               |

**Figure 19.3 Mailbox-N Structure (continued)**

- Notes:
1. All bits shadowed in grey are reserved and must be written LOW. The value returned by a read may not always be '0' and should not be relied upon.
  2. ATX and DART are not supported by Mailbox-0, and the MBC setting of Mailbox-0 is limited.
  3. ID Reorder (MCR15) can change the order of STDID, RTR, IDE and EXTID of both message control and LAFM.

## (1) Message Control Field

**STIDID[10:0]:** These bits set the identifier (standard identifier) of data frames and remote frames.

**EXTID[17:0]:** These bits set the identifier (extended identifier) of data frames and remote frames.

**RTR** (Remote Transmission Request bit): Used to distinguish between data frames and remote frames. This bit is overwritten by received CAN Frames depending on Data Frames or Remote Frames.

**Important:** Please note that, when ATX bit is set with the setting MBC = 001(bin), the RTR bit will never be set. When a Remote Frame is received, the CPU can be notified by the corresponding RFPR set or IRR[2] (Remote Frame Receive Interrupt), however, as RCAN-TL1 needs to transmit the current message as a Data Frame, the RTR bit remains unchanged.

**Important:** In order to support automatic answer to remote frame when MBC = 001 (bin) is used and ATX = 1 the RTR flag must be programmed to zero to allow data frame to be transmitted.

Note: when a Mailbox is configured to send a remote frame request the DLC used for transmission is the one stored into the Mailbox.

| RTR | Description  |
|-----|--------------|
| 0   | Data frame   |
| 1   | Remote frame |

**IDE** (Identifier Extension bit): Used to distinguish between the standard format and extended format of CAN data frames and remote frames.

| IDE | Description     |
|-----|-----------------|
| 0   | Standard format |
| 1   | Extended format |

- Mailbox-0

|                |    |    |     |    |    |          |   |     |   |   |   |   |          |     |     |     |
|----------------|----|----|-----|----|----|----------|---|-----|---|---|---|---|----------|-----|-----|-----|
| Bit:           | 15 | 14 | 13  | 12 | 11 | 10       | 9 | 8   | 7 | 6 | 5 | 4 | 3        | 2   | 1   | 0   |
|                | 0  | 0  | NMC | 0  | 0  | MBC[2:0] |   |     | 0 | 0 | 0 | 0 | DLC[3:0] |     |     |     |
| Initial value: | 0  | 0  | 0   | 0  | 0  | 1        | 1 | 1   | 0 | 0 | 0 | 0 | 0        | 0   | 0   | 0   |
| R/W:           | R  | R  | R/W | R  | R  | R/W      | R | R/W | R | R | R | R | R/W      | R/W | R/W | R/W |

Note: MBC[1] of MB0 is always "1".

- Mailbox-31 to 1

|                |    |    |     |     |      |          |     |     |   |   |   |   |          |     |     |     |
|----------------|----|----|-----|-----|------|----------|-----|-----|---|---|---|---|----------|-----|-----|-----|
| Bit:           | 15 | 14 | 13  | 12  | 11   | 10       | 9   | 8   | 7 | 6 | 5 | 4 | 3        | 2   | 1   | 0   |
|                | 0  | 0  | NMC | ATX | DART | MBC[2:0] |     |     | 0 | 0 | 0 | 0 | DLC[3:0] |     |     |     |
| Initial value: | 0  | 0  | 0   | 0   | 0    | 1        | 1   | 1   | 0 | 0 | 0 | 0 | 0        | 0   | 0   | 0   |
| R/W:           | R  | R  | R/W | R/W | R/W  | R/W      | R/W | R/W | R | R | R | R | R/W      | R/W | R/W | R/W |

**NMC (New Message Control):** When this bit is set to '0', the Mailbox of which the RXPR or RFPR bit is already set does not store the new message but maintains the old one and sets the UMSR correspondent bit. When this bit is set to '1', the Mailbox of which the RXPR or RFPR bit is already set overwrites with the new message and sets the UMSR correspondent bit.

**Important:** Please note that if a remote frame is overwritten with a data frame or vice versa could be that both RXPR and RFPR flags (together with UMSR) are set for the same Mailbox. In this case the RTR bit within the Mailbox Control Field should be relied upon.

**Important:** Please note that when the Time Triggered mode is used NMC needs to be set to '1' for Mailbox 31 to allow synchronization with all incoming reference messages even when RXPR[31] is not cleared.

| NMC | Description                  |
|-----|------------------------------|
| 0   | Overrun mode (Initial value) |
| 1   | Overwrite mode               |

**ATX (Automatic Transmission of Data Frame):** When this bit is set to '1' and a Remote Frame is received into the Mailbox DLC is stored. Then, a Data Frame is transmitted from the same Mailbox using the current contents of the message data and updated DLC by setting the corresponding TXPR automatically. The scheduling of transmission is still governed by ID priority or Mailbox priority as configured with the Message Transmission Priority control bit (MCR.2). In order to use this function, MBC[2:0] needs to be programmed to be '001' (Bin). When a transmission is performed by this function, the DLC (Data Length Code) to be used is the one that has been received. Application needs to guarantee that the DLC of the remote frame correspond to the DLC of the data frame requested.

**Important:** When ATX is used and MBC = 001 (Bin) the filter for the IDE bit cannot be used since ID of remote frame has to be exactly the same as that of data frame as the reply message.

**Important:** Please note that, when this function is used, the RTR bit will never be set despite receiving a Remote Frame. When a Remote Frame is received, the CPU will be notified by the corresponding RFPR set, however, as RCAN-TL1 needs to transmit the current message as a Data Frame, the RTR bit remains unchanged.

**Important:** Please note that in case of overrun condition (UMSR flag set when the Mailbox has its NMC = 0) the message received is discarded. In case a remote frame is causing overrun into a Mailbox configured with ATX = 1, the transmission of the corresponding data frame may be triggered only if the related PFPR flag is cleared by the CPU when the UMSR flag is set. In such case PFPR flag would get set again.

| ATX | Description                                                   |
|-----|---------------------------------------------------------------|
| 0   | Automatic Transmission of Data Frame disabled (Initial value) |
| 1   | Automatic Transmission of Data Frame enabled                  |

**DART (Disable Automatic Re-Transmission):** When this bit is set, it disables the automatic re-transmission of a message in the event of an error on the CAN bus or an arbitration lost on the CAN bus. In effect, when this function is used, the corresponding TXCR bit is automatically set at the start of transmission. When this bit is set to '0', RCAN-TL1 tries to transmit the message as many times as required until it is successfully transmitted or it is cancelled by the TXCR.

| DART | Description                             |
|------|-----------------------------------------|
| 0    | Re-transmission enabled (Initial value) |
| 1    | Re-Transmission disabled                |

**MBC[2:0] (Mailbox Configuration):** These bits configure the nature of each Mailbox as follows. When MBC = 111 (Bin), the Mailbox is inactive, i.e., it does not receive or transmit a message regardless of TXPR or other settings. The MBC = '110', '101' and '100' settings are prohibited. When the MBC is set to any other value, the LAFM field becomes available. Please don't set TXPR when MBC is set as reception as there is no hardware protection, and TXPR will remain set. MBC[1] of Mailbox-0 is fixed to "1" by hardware. This is to ensure that MB0 cannot be configured to transmit Messages.

| MBC[2] | MBC[1] | MBC[0] | Data<br>Frame<br>Transmit        | Remote<br>Frame<br>Transmit | Data<br>Frame<br>Receive | Remote<br>Frame<br>Receive | Remarks                                                                                                                              |

| 1      | 0      | 0      | Setting prohibited               |                             |                          |                            |                                                                                                                                      |
| 1      | 0      | 1      | Setting prohibited               |                             |                          |                            |                                                                                                                                      |
| 1      | 1      | 0      | Setting prohibited               |                             |                          |                            |                                                                                                                                      |
| 1      | 1      | 1      | Mailbox inactive (Initial value) |                             |                          |                            |                                                                                                                                      |

Notes: \* In order to support automatic retransmission, RTR shall be "0" when MBC = 001(bin) and ATX = 1.

When ATX = 1 is used the filter for IDE must not be used.

**DLC[3:0] (Data Length Code):** These bits encode the number of data bytes from 0, 1, 2, ... 8 that will be transmitted in a data frame. Please note that when a remote frame request is transmitted the DLC value to be used must be the same as the DLC of the data frame that is requested.

| DLC[3] | DLC[2] | DLC[1] | DLC[0] | Description                           |
|--------|--------|--------|--------|---------------------------------------|
| 0      | 0      | 0      | 0      | Data Length = 0 bytes (Initial value) |
| 0      | 0      | 0      | 1      | Data Length = 1 byte                  |
| 0      | 0      | 1      | 0      | Data Length = 2 bytes                 |
| 0      | 0      | 1      | 1      | Data Length = 3 bytes                 |
| 0      | 1      | 0      | 0      | Data Length = 4 bytes                 |
| 0      | 1      | 0      | 1      | Data Length = 5 bytes                 |
| 0      | 1      | 1      | 0      | Data Length = 6 bytes                 |
| 0      | 1      | 1      | 1      | Data Length = 7 bytes                 |
| 1      | x      | x      | x      | Data Length = 8 bytes                 |

## (2) Local Acceptance Filter Mask (LAFM)

This area is used as Local Acceptance Filter Mask (LAFM) for receive boxes.

**LAFM:** When MBC is set to 001, 010, 011(Bin), this field is used as LAFM Field. It allows a Mailbox to accept more than one identifier. The LAFM is comprised of two 16-bit read/write areas as follows.

|              |                  |    |    |                  |    |    |   |   |   |   |   |   |      |                      |   |         |  |            |
|--------------|------------------|----|----|------------------|----|----|---|---|---|---|---|---|------|----------------------|---|---------|--|------------|
|              | 15               | 14 | 13 | 12               | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3    | 2                    | 1 | 0       |  |            |
| H'104 + N*32 | IDE<br>LAFM      | 0  | 0  | STDID_LAFM[10:0] |    |    |   |   |   |   |   |   |      | EXTID<br>LAFM[17:16] |   | Word/LW |  | LAFM Field |
| H'106 + N*32 | EXTID_LAFM[15:0] |    |    |                  |    |    |   |   |   |   |   |   | Word |                      |   |         |  |            |

**Figure 19.4 Acceptance filter**

If a bit is set in the LAFM, then the corresponding bit of a received CAN identifier is ignored when the RCAN-TL1 searches a Mailbox with the matching CAN identifier. If the bit is cleared, then the corresponding bit of a received CAN identifier must match to the STDID/IDE/EXTID set in the mailbox to be stored. The structure of the LAFM is same as the message control in a Mailbox. If this function is not required, it must be filled with '0'.

**Important:** RCAN-TL1 starts to find a matching identifier from Mailbox-31 down to Mailbox-0. As soon as RCAN-TL1 finds one matching, it stops the search. The message will be stored or not depending on the NMC and RXPR/RFPD flags. This means that, even using LAFM, a received message can only be stored into 1 Mailbox.

**Important:** When a message is received and a matching Mailbox is found, the whole message is stored into the Mailbox. This means that, if the LAFM is used, the STDID, RTR, IDE and EXTID may differ to the ones originally set as they are updated with the STDID, RTR, IDE and EXTID of the received message.

**STD\_LAFM[10:0]** — Filter mask bits for the CAN base identifier [10:0] bits.

| <b>STD_LAFM[10:0]</b> | <b>Description</b>                        |
|-----------------------|-------------------------------------------|
| 0                     | Corresponding STD_ID bit is cared         |
| 1                     | Corresponding STD_ID bit is "don't cared" |

**EXT\_LAFM[17:0]** — Filter mask bits for the CAN Extended identifier [17:0] bits.

| <b>EXT_LAFM[17:0]</b> | <b>Description</b>                        |
|-----------------------|-------------------------------------------|
| 0                     | Corresponding EXT_ID bit is cared         |
| 1                     | Corresponding EXT_ID bit is "don't cared" |

**IDE\_LAFM** — Filter mask bit for the CAN IDE bit.

| <b>IDE_LAFM</b> | <b>Description</b>                     |
|-----------------|----------------------------------------|
| 0               | Corresponding IDE bit is cared         |
| 1               | Corresponding IDE bit is "don't cared" |

### (3) Message Data Fields

Storage for the CAN message data that is transmitted or received. MSG\_DATA[0] corresponds to the first data byte that is transmitted or received. The bit order on the CAN bus is bit 7 through to bit 0.

When CMAX!= 3'b111/MBC[30] = 3'b000 and TXPR[30] is set, Mailbox-30 is configured as transmission of time reference. Its DLC must be greater than 0 and its RTR must be zero (as specified for TTCAN Level 1) so that the Cycle\_count (CCR register) is embedded in the first byte of the data field instead of MSG\_DATA\_0[5:0] when this Mailbox starts transmission. This function shall be used when RCAN-TL1 is enabled to work in TTCAN mode to perform a Potential Time Master role to send the Time reference message. MSG\_DATA\_0[7:6] is still transmitted as stored in the Mailbox. User can set MSG\_DATA\_0[7] when a Next\_is\_Gap needs to be transmitted.

Please note that the CCR value is only embedded on the frame transmitted but not stored back into Mailbox 30.

When  $C_{MAX} \neq 3'b111$ ,  $MBC[31] = 3'b011$  and  $TXPR[31]$  is cleared, Mailbox-31 is configured as reception of time reference. When a valid reference message is received ( $DLC > 0$ ) RCAN-TL1 performs internal synchronisation (modifying its RFMK and basic cycle CCR).

| MB30 - 31    |                                              |    |    |    |    |    |   |   |            |   |   |   |   |   |   |   |              |      |
|--------------|----------------------------------------------|----|----|----|----|----|---|---|------------|---|---|---|---|---|---|---|--------------|------|
|              | 15                                           | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7          | 6 | 5 | 4 | 3 | 2 | 1 | 0 |              |      |
| H'108 + N*32 | Next_is_Gap/Cycle_Counter (first Rx/Tx Byte) |    |    |    |    |    |   |   | MSG_DATA_1 |   |   |   |   |   |   |   | Byte/Word/LW | Data |
| H'10A + N*32 | MSG_DATA_2                                   |    |    |    |    |    |   |   | MSG_DATA_3 |   |   |   |   |   |   |   | Byte/Word    |      |
| H'10C + N*32 | MSG_DATA_4                                   |    |    |    |    |    |   |   | MSG_DATA_5 |   |   |   |   |   |   |   | Byte/Word/LW |      |
| H'10E + N*32 | MSG_DATA_6                                   |    |    |    |    |    |   |   | MSG_DATA_7 |   |   |   |   |   |   |   | Byte/Word    |      |

**Figure 19.5 Message Data Field**

#### (4) Timestamp

Storage for the Timestamp recorded on messages for transmit/receive. The Timestamp will be a useful function to monitor if messages are received/transmitted within expected schedule.

- Timestamp

| Bit:           | 15   | 14   | 13   | 12   | 11   | 10   | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|----------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|                | TS15 | TS14 | TS13 | TS12 | TS11 | TS10 | TS9 | TS8 | TS7 | TS6 | TS5 | TS4 | TS3 | TS2 | TS1 | TS0 |
| Initial value: | 0    | 0    | 0    | 0    | 0    | 0    | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| R/W:           | R    | R    | R    | R    | R    | R    | R   | R   | R   | R   | R   | R   | R   | R   | R   | R   |

**Message Receive:** For received messages of Mailbox-15 to 0, Timestamp always captures the CYCTR (Cycle Time Register) value or Cycle\_Counter  $CCR[5:0] + CYCTR[15:6]$  value, depending on the programmed value in the bit 14 of TTCR0 (Timer Trigger Control Register 0) at SOF.

For messages received into Mailboxes 30 and 31, Timestamp captures the TCNTR (Timer Counter Register) value at SOF.

**Message Transmit:** For transmitted messages of Mailbox-15 to 1, Timestamp always captures the CYCTR (Cycle Time Register) value or Cycle\_Counter  $CCR[5:0] + CYCTR[15:6]$  value, depending on the programmed value in the bit 14 of TTCR0 (Timer Trigger Control Register 0), at SOF.

For messages transmitted from Mailboxes 30 and 31, Timestamp captures the TCNTR (Timer Counter Register) value at SOF.

**Important:** Please note that the TimeStamp is stored in a temporary register. Only after a successful transmission or reception the value is then copied into the related Mailbox field. The TimeStamp may also be updated if the CPU clears RXPR[N]/RFPR[N] at the same time that UMSR[N] is set in overrun, however it can be read properly before clearing RXPR[N]/RFPR[N].

### (5) Tx-Trigger Time (TTT) and Time Trigger control

For Mailbox-29 to 24, when MBC is set to 000 (Bin) in time trigger mode (CMA<sub>X</sub>!= 3'b111), Tx-Trigger Time works as Time\_Mark to determine the boundary between time windows. The TTT and TT control are comprised of two 16-bit read/write areas as follows. Mailbox-30 doesn't have TT control and works as Time\_Ref.

Mailbox 30 to 24 can be used for reception if not used for transmission in TT mode. However they cannot join the event trigger transmission queue when the TT mode is used.

- Tx-Trigger Time

|                |       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|----------------|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| Bit:           | 15    | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|                | TTT15 | TTT14 | TTT13 | TTT12 | TTT11 | TTT10 | TTT9 | TTT8 | TTT7 | TTT6 | TTT5 | TTT4 | TTT3 | TTT2 | TTT1 | TTT0 |
| Initial value: | 0     | 0     | 0     | 0     | 0     | 0     | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |
| R/W:           | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |

- Time Trigger control

|                |          |     |             |     |     |     |     |     |   |   |   |   |                 |     |     |     |
|----------------|----------|-----|-------------|-----|-----|-----|-----|-----|---|---|---|---|-----------------|-----|-----|-----|
| Bit:           | 15       | 14  | 13          | 12  | 11  | 10  | 9   | 8   | 7 | 6 | 5 | 4 | 3               | 2   | 1   | 0   |
|                | TTW[1:0] |     | Offset[5:0] |     |     |     |     | 0   | 0 | 0 | 0 | 0 | rep_factor[2:0] |     |     |     |
| Initial value: | 0        | 0   | 0           | 0   | 0   | 0   | 0   | 0   | 0 | 0 | 0 | 0 | 0               | 0   | 0   | 0   |
| R/W:           | R/W      | R/W | R/W         | R/W | R/W | R/W | R/W | R/W | R | R | R | R | R               | R/W | R/W | R/W |

The following figure shows the differences between all Mailboxes supporting Time Triggered mode.

Figure 19.6 Tx-Trigger control field

- **TTW[1:0] (Time Trigger Window):** These bits show the attribute of time windows. Please note that once a merged arbitrating window is opened by  $TTW = 2'b10$ , the window must be closed by  $TTW = 2'b11$ . Several messages with  $TTW = 2'b10$  may be used within the start and the end of a merged arbitrating window.

| TTW[1] | TTW[0] | Description                        |
|--------|--------|------------------------------------|
| 0      | 0      | Exclusive window (initial value)   |
| 0      | 1      | Arbitrating window                 |
| 1      | 0      | Start of merged arbitrating window |
| 1      | 1      | End of merged arbitrating window   |

The first 16-bit area specifies the time that triggers the transmission of the message in cycle time. The second 16-bit area specifies the basic cycle in the system matrix where the transmission must start (Offset) and the frequency for periodic transmission. When the internal TTT register matches to the CYCTR value, and the internal Offset matches to CCR value transmission is attempted from the corresponding Mailbox. In order to enable this function, the CMAX (Cycle Maximum Register) must be set to a value different from  $3'b111$ , the Timer (TCNTR) must be running (TTCR0 bit15 = 1), the corresponding MBC must be set to  $3'b000$  and the corresponding TXPR bit must be set. Once TXPR is set by S/W, RCAN-TL1 does not clear the corresponding TXPR bit (among Mailbox-30 to 24) to carry on performing the periodic transmission. In order to stop the periodic transmission, TXPR must be cleared by TXCR. Please note that in this case it is possible that both TXACK and ABACK are set for the same Mailbox if TXACK is not cleared right after completion of transmission. Please refer to figure 19.7.

**Figure 19.7 TXACK and ABACK in Time Trigger Transmission**

Please note that for Mailbox 30 TTW is fixed to '01', Offset to '00' and rep\_factor to '0'. The following tables report the combinations for the rep\_factor and the offset.

| Rep_factor | Description                                          |
|------------|------------------------------------------------------|
| 3'b000     | Every basic cycle (initial value)                    |
| 3'b001     | Every two basic cycle                                |
| 3'b010     | Every four basic cycle                               |
| 3'b011     | Every eight basic cycle                              |
| 3'b100     | Every sixteen basic cycle                            |
| 3'b101     | Every thirty two basic cycle                         |
| 3'b110     | Every sixty four basic cycle (once in system matrix) |
| 3'b111     | Reserved                                             |

The Offset Field determines the first cycle in which a Time Triggered Mailbox may start transmitting its Message.

| Offset    | Description                                                  |
|-----------|--------------------------------------------------------------|
| 6'b000000 | Initial Offset = 1 <sup>st</sup> Basic Cycle (initial value) |
| 6'b000001 | Initial Offset = 2 <sup>nd</sup> Basic Cycles                |
| 6'b000010 | Initial Offset = 3 <sup>rd</sup> Basic Cycles                |
| 6'b000011 | Initial Offset = 4 <sup>th</sup> Basic Cycles                |
| 6'b000100 | Initial Offset = 5 <sup>th</sup> Basic Cycles                |
| ...       |                                                              |
| ...       |                                                              |
| 6'b111110 | Initial Offset = 63 <sup>rd</sup> Basic Cycles               |
| 6'b111111 | Initial Offset = 64 <sup>th</sup> Basic Cycles               |

**The following relation must be maintained:**

$$\text{Cycle\_Count\_Maximum} + 1 \geq \text{Repeat\_Factor} > \text{Offset}$$

$$\text{Cycle\_Count\_Maximum} = 2^{\text{CMAX}} - 1$$

$$\text{Repeat\_Factor} = 2^{\text{rep\_factor}}$$

CMAX, Repeat\_Factor, and Offset are register values

**Figure 19.8 System Matrix**

The Tx-Trigger Time must be set in ascending order. Please bear in mind that a minimum difference of TEW's width between Tx-Trigger Times is allowed.

19.3.3    RCAN-TL1 Control Registers

The following sections describe RCAN-TL1 control registers. The address is mapped as follow.

**Important:** These registers can only be accessed in Word size (16-bit).

| Description                  | Address | Name    | Access Size (bits) |
|------------------------------|---------|---------|--------------------|
| Master Control Register      | 000     | MCR     | Word               |
| General Status Register      | 002     | GSR     | Word               |
| Bit Configuration Register 1 | 004     | BCR1    | Word               |
| Bit Configuration Register 0 | 006     | BCR0    | Word               |
| Interrupt Register           | 008     | IRR     | Word               |
| Interrupt Mask Register      | 00A     | IMR     | Word               |
| Error Counter Register       | 00C     | TEC/REC | Word               |

Figure 19.9    RCAN-TL1 control registers

(1)    Master Control Register (MCR)

The Master Control Register (MCR) is a 16-bit read/write register that controls RCAN-TL1.

- MCR (Address = H'000)

|                |       |       |    |    |    |          |     |      |      |      |     |   |      |      |      |     |
|----------------|-------|-------|----|----|----|----------|-----|------|------|------|-----|---|------|------|------|-----|

Figure 19.10 ID Reorder

This bit can be modified only in reset mode.

**Bit 14 — Auto Halt Bus Off (MCR14):** If both this bit and MCR6 are set, MCR1 is automatically set as soon as RCAN-TL1 enters BusOff.

| Bit14: MCR14 | Description |
|--------------|-------------|
|--------------|-------------|

|   |                                                                                                   |
|---|---------------------------------------------------------------------------------------------------|
| 0 | RCAN-TL1 remains in BusOff for normal recovery sequence (128 x 11 Recessive Bits) (Initial value) |
| 1 | RCAN-TL1 moves directly into Halt Mode after it enters BusOff if MCR6 is set.                     |

This bit can be modified only in reset mode.

**Bit 13 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 12 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 11 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 10 to 8 — Test Mode (TST[2:0]):** This bit enables/disables the test modes. Please note that before activating the Test Mode it is requested to move RCAN-TL1 into Halt mode or Reset mode. This is to avoid that the transition to Test Mode could affect a transmission/reception in progress. For details, please refer to section 19.4.1, Test Mode Settings.

Please note that the test modes are allowed only for diagnosis and tests and not when RCAN-TL1 is used in normal operation.

| Bit10:<br>TST2 | Bit9:<br>TST1 | Bit8:<br>TST0 | Description                          |
|----------------|---------------|---------------|--------------------------------------|
| 0              | 0             | 0             | Normal Mode (initial value)          |
| 0              | 0             | 1             | Listen-Only Mode (Receive-Only Mode) |
| 0              | 1             | 0             | Self Test Mode 1 (External)          |
| 0              | 1             | 1             | Self Test Mode 2 (Internal)          |
| 1              | 0             | 0             | Write Error Counter                  |
| 1              | 0             | 1             | Error Passive Mode                   |
| 1              | 1             | 0             | Setting prohibited                   |
| 1              | 1             | 1             | Setting prohibited                   |

**Bit 7 — Auto-wake Mode (MCR7):** MCR7 enables or disables the Auto-wake mode. If this bit is set, the RCAN-TL1 automatically cancels the sleep mode (MCR5) by detecting CAN bus activity (dominant bit). If MCR7 is cleared the RCAN-TL1 does not automatically cancel the sleep mode.

RCAN-TL1 cannot store the message that wakes it up.

Note: This bit can be modified only Reset or Halt mode.

| Bit7: MCR7 | Description                                            |
|------------|--------------------------------------------------------|
| 0          | Auto-wake by CAN bus activity disabled (Initial value) |
| 1          | Auto-wake by CAN bus activity enabled                  |

**Bit 6 — Halt during Bus Off (MCR6):** MCR6 enables or disables entering Halt mode immediately when MCR1 is set during Bus Off. This bit can be modified only in Reset or Halt mode. Please note that when Halt is entered in Bus Off the CAN engine is also recovering immediately to Error Active mode.

| Bit6: MCR6 | Description                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------|
| 0          | If MCR[1] is set, RCAN-TL1 will not enter Halt mode during Bus Off but wait up to end of recovery sequence (Initial value) |
| 1          | Enter Halt mode immediately during Bus Off if MCR[1] or MCR[14] are asserted.                                              |

**Bit 5 — Sleep Mode (MCR5):** Enables or disables Sleep mode transition. If this bit is set, while RCAN-TL1 is in halt mode, the transition to sleep mode is enabled. Setting MCR5 is allowed after entering Halt mode. The two Error Counters (REC, TEC) will remain the same during Sleep mode. This mode will be exited in two ways:

1. by writing a '0' to this bit position,
2. or, if MCR[7] is enabled, after detecting a dominant bit on the CAN bus.

If Auto wake up mode is disabled, RCAN-TL1 will ignore all CAN bus activities until the sleep mode is terminated. When leaving this mode the RCAN-TL1 will synchronise to the CAN bus (by checking for 11 recessive bits) before joining CAN Bus activity. This means that, when the No.2 method is used, RCAN-TL1 will miss the first message to receive. CAN transceivers stand-by mode will also be unable to cope with the first message when exiting stand by mode, and the S/W needs to be designed in this manner.

In sleep mode only the following registers can be accessed: MCR, GSR, IRR and IMR.

**Important:** RCAN-TL1 is required to be in Halt mode before requesting to enter in Sleep mode. That allows the CPU to clear all pending interrupts before entering sleep mode. Once all interrupts are cleared RCAN-TL1 must leave the Halt mode and enter Sleep mode simultaneously (by writing MCR[5] = 1 and MCR[1] = 0 at the same time).

| Bit 5: MCR5 | Description                                  |
|-------------|----------------------------------------------|
| 0           | RCAN-TL1 sleep mode released (Initial value) |
| 1           | Transition to RCAN-TL1 sleep mode enabled    |

**Bit 4 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 3 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 2 — Message Transmission Priority (MCR2):** MCR2 selects the order of transmission for pending transmit data. If this bit is set, pending transmit data are sent in order of the bit position in the Transmission Pending Register (TXPR). The order of transmission starts from Mailbox-31 as the highest priority, and then down to Mailbox-1 (if those mailboxes are configured for transmission). Please note that this feature cannot be used for time trigger transmission of the Mailboxes 24 to 30.

If MCR2 is cleared, all messages for transmission are queued with respect to their priority (by running internal arbitration). The highest priority message has the Arbitration Field (STDID + IDE bit + EXTID (if IDE = 1) + RTR bit) with the lowest digital value and is transmitted first. The internal arbitration includes the RTR bit and the IDE bit (internal arbitration works in the same

way as the arbitration on the CAN Bus between two CAN nodes starting transmission at the same time).

This bit can be modified only in Reset or Halt mode.

| Bit 2: MCR2 | Description                                                                       |
|-------------|-----------------------------------------------------------------------------------|
| 0           | Transmission order determined by message identifier priority (Initial value)      |
| 1           | Transmission order determined by mailbox number priority (Mailbox-31 → Mailbox-1) |

**Bit 1—Halt Request (MCR1):** Setting the MCR1 bit causes the CAN controller to complete its current operation and then enter Halt mode (where it is cut off from the CAN bus). The RCAN-TL1 remains in Halt Mode until the MCR1 is cleared. During the Halt mode, the CAN Interface does not join the CAN bus activity and does not store messages or transmit messages. All the user registers (including Mailbox contents and TEC/REC) remain unchanged with the exception of IRR0 and GSR4 which are used to notify the halt status itself. If the CAN bus is in idle or intermission state regardless of MCR6, RCAN-TL1 will enter Halt Mode within one Bit Time. If MCR6 is set, a halt request during Bus Off will be also processed within one Bit Time. Otherwise the full Bus Off recovery sequence will be performed beforehand. Entering the Halt Mode can be notified by IRR0 and GSR4.

If both MCR14 and MCR6 are set, MCR1 is automatically set as soon as RCAN-TL1 enters BusOff.

In the Halt mode, the RCAN-TL1 configuration can be modified with the exception of the Bit Timing setting, as it does not join the bus activity. MCR[1] has to be cleared by writing a '0' in order to re-join the CAN bus. After this bit has been cleared, RCAN-TL1 waits until it detects 11 recessive bits, and then joins the CAN bus.

- Notes:
1. After issuing a Halt request the CPU is not allowed to set TXPR or TXCR or clear MCR1 until the transition to Halt mode is completed (notified by IRR0 and GSR4). After MCR1 is set this can be cleared only after entering Halt mode or through a reset operation (SW or HW).
  2. Transition into or recovery from HALT mode, is only possible if the BCR1 and BCR0 registers are configured to a proper Baud Rate.

| Bit 1: MCR1 | Description                        |
|-------------|------------------------------------|
| 0           | Clear Halt request (Initial value) |
| 1           | Halt mode transition request       |

**Bit 0 — Reset Request (MCR0):** Controls resetting of the RCAN-TL1 module. When this bit is changed from ‘0’ to ‘1’ the RCAN-TL1 controller enters its reset routine, re-initialising the internal logic, which then sets GSR3 and IRR0 to notify the reset mode. During a re-initialisation, all user registers are initialised.

RCAN-TL1 can be re-configured while this bit is set. This bit has to be cleared by writing a ‘0’ to join the CAN bus. After this bit is cleared, the RCAN-TL1 module waits until it detects 11 recessive bits, and then joins the CAN bus. The Baud Rate needs to be set up to a proper value in order to sample the value on the CAN Bus.

After Power On Reset, this bit and GSR3 are always set. This means that a reset request has been made and RCAN-TL1 needs to be configured.

The Reset Request is equivalent to a Power On Reset but controlled by Software.

| Bit 0: MCR0 | Description                                                 |
|-------------|-------------------------------------------------------------|
| 0           | Clear Reset Request                                         |
| 1           | CAN Interface reset mode transition request (Initial value) |

(2) General Status Register (GSR)

The General Status Register (GSR) is a 16-bit read-only register that indicates the status of RCAN-TL1.

- GSR (Address = H'002)

|                |    |    |    |    |    |    |   |   |   |   |      |      |      |      |      |      |
|----------------|----|----|----|----|----|----|---|---|---|---|------|------|------|------|------|------|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5    | 4    | 3    | 2    | 1    | 0    |
|                | -  | -  | -  | -  | -  | -  | - | - | - | - | GSR5 | GSR4 | GSR3 | GSR2 | GSR1 | GSR0 |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0    | 0    | 1    | 1    | 0    | 0    |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R | R | R    | R    | R    | R    | R    | R    |

**Bits 15 to 6: Reserved.** The written value should always be ‘0’ and the returned value is ‘0’.

**Bit 5 — Error Passive Status Bit (GSR5):** Indicates whether the CAN Interface is in Error Passive or not. This bit will be set high as soon as the RCAN-TL1 enters the Error Passive state and is cleared when the module enters again the Error Active state (this means the GSR5 will stay high during Error Passive and during Bus Off). Consequently to find out the correct state both GSR5 and GSR0 must be considered.

| Bit 5: GSR5 | Description                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | RCAN-TL1 is not in Error Passive or in Bus Off status (Initial value)<br>[Reset condition] RCAN-TL1 is in Error Active state                                               |
| 1           | RCAN-TL1 is in Error Passive (if GSR0 = 0) or Bus Off (if GSR0 = 1)<br>[Setting condition] When $TEC \geq 128$ or $REC \geq 128$ or if Error Passive Test Mode is selected |

**Bit 4 — Halt/Sleep Status Bit (GSR4):** Indicates whether the CAN engine is in the halt/sleep state or not. Please note that the clearing time of this flag is not the same as the setting time of IRR12.

Please note that this flag reflects the status of the CAN engine and not of the full RCAN-TL1 IP. RCAN-TL1 exits sleep mode and can be accessed once MCR5 is cleared. The CAN engine exits sleep mode only after two additional transmission clocks on the CAN Bus.

| Bit 4: GSR4 | Description                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | RCAN-TL1 is not in the Halt state or Sleep state (Initial value)                                                                                                                                                                                              |
| 1           | Halt mode (if MCR1 = 1) or Sleep mode (if MCR5 = 1)<br>[Setting condition] If MCR1 is set and the CAN bus is either in intermission or idle or MCR5 is set and RCAN-TL1 is in the halt mode or RCAN-TL1 is moving to Bus Off when MCR14 and MCR6 are both set |

**Bit 3 — Reset Status Bit (GSR3):** Indicates whether the RCAN-TL1 is in the reset state or not.

| Bit 3: GSR3 | Description                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------|
| 0           | RCAN-TL1 is not in the reset state                                                                          |
| 1           | Reset state (Initial value)<br>[Setting condition] After an RCAN-TL1 internal reset (due to SW or HW reset) |

**Bit 2 — Message Transmission in progress Flag (GSR2):** Flag that indicates to the CPU if the RCAN-TL1 is in Bus Off or transmitting a message or an error/overload flag due to error detected during transmission. The timing to set TXACK is different from the time to clear GSR2. TXACK is set at the 7<sup>th</sup> bit of End Of Frame. GSR2 is set at the 3<sup>rd</sup> bit of intermission if there are no more messages ready to be transmitted. It is also set by arbitration lost, bus idle, reception, reset or halt transition.

| Bit 2: GSR2 | Description                                                                           |
|-------------|---------------------------------------------------------------------------------------|
| 0           | RCAN-TL1 is in Bus Off or a transmission is in progress                               |
| 1           | [Setting condition]<br>Not in Bus Off and no transmission in progress (Initial value) |

**Bit 1—Transmit/Receive Warning Flag (GSR1):** Flag that indicates an error warning.

| Bit 1: GSR1 | Description                                                                       |
|-------------|-----------------------------------------------------------------------------------|
| 0           | [Reset condition] When (TEC < 96 and REC < 96) or Bus Off (Initial value)         |
| 1           | [Setting condition] When $96 \leq \text{TEC} < 256$ or $96 \leq \text{REC} < 256$ |

Note: REC is incremented during Bus Off to count the recurrences of 11 recessive bits as requested by the Bus Off recovery sequence. However the flag GSR1 is not set in Bus Off.

**Bit 0—Bus Off Flag (GSR0):** Flag that indicates that RCAN-TL1 is in the bus off state.

| Bit 0: GSR0 | Description                                                                                |
|-------------|--------------------------------------------------------------------------------------------|
| 0           | [Reset condition]<br>Recovery from bus off state or after a HW or SW reset (Initial value) |
| 1           | [Setting condition] When $\text{TEC} \geq 256$ (bus off state)                             |

Note: Only the lower 8 bits of TEC are accessible from the user interface. The 9<sup>th</sup> bit is equivalent to GSR0.

(3) Bit Configuration Register (BCR0, BCR1)

The bit configuration registers (BCR0 and BCR1) are 2 X 16-bit read/write register that are used to set CAN bit timing parameters and the baud rate pre-scaler for the CAN Interface.

The Time quanta is defined as:

$$Timequanta = \frac{2 * BRP}{f_{clk}}$$

Where: BRP (Baud Rate Pre-scaler) is the value stored in BCR0 incremented by 1 and fclk is the used peripheral clock frequency.

- BCR1 (Address = H'004)

|                |           |     |     |     |    |           |     |     |   |   |          |     |   |   |   |     |
|----------------|-----------|-----|-----|-----|----|-----------|-----|-----|---|---|----------|-----|---|---|---|-----|
| Bit:           | 15        | 14  | 13  | 12  | 11 | 10        | 9   | 8   | 7 | 6 | 5        | 4   | 3 | 2 | 1 | 0   |
|                | TSG1[3:0] |     |     |     | -  | TSG2[2:0] |     |     | - | - | SJW[1:0] |     | - | - | - | BSP |
| Initial value: | 0         | 0   | 0   | 0   | 0  | 0         | 0   | 0   | 0 | 0 | 0        | 0   | 0 | 0 | 0 | 0   |
| R/W:           | R/W       | R/W | R/W | R/W | R  | R/W       | R/W | R/W | R | R | R/W      | R/W | R | R | R | R/W |

**Bits 15 to 12 — Time Segment 1 (TSG1[3:0] = BCR1[15:12]):** These bits are used to set the segment TSEG1 (= PRSEG + PHSEG1) to compensate for edges on the CAN Bus with a positive phase error. A value from 4 to 16 time quanta can be set.

**Bit 15: Bit 14: Bit 13: Bit 12:**  
**TSG1[3] TSG1[2] TSG1[1] TSG1[0] Description**

|   |   |   |   |                                    |
|---|---|---|---|------------------------------------|
| 0 | 0 | 0 | 0 | Setting prohibited (Initial value) |
| 0 | 0 | 0 | 1 | Setting prohibited                 |
| 0 | 0 | 1 | 0 | Setting prohibited                 |
| 0 | 0 | 1 | 1 | PRSEG + PHSEG1 = 4 time quanta     |
| 0 | 1 | 0 | 0 | PRSEG + PHSEG1 = 5 time quanta     |
| : | : | : | : | :                                  |
| : | : | : | : | :                                  |
| 1 | 1 | 1 | 1 | PRSEG + PHSEG1 = 16 time quanta    |

**Bit 11: Reserved.** The written value should always be ‘0’ and the returned value is ‘0’.

**Bits 10 to 8 — Time Segment 2 (TSG2[2:0] = BCR1[10:8]):** These bits are used to set the segment TSEG2 (= PHSEG2) to compensate for edges on the CAN Bus with a negative phase error. A value from 2 to 8 time quanta can be set as shown below.

| Bit 10:<br>TSG2[2] | Bit 9:<br>TSG2[1] | Bit 8:<br>TSG2[0] | Description                                       |
|--------------------|-------------------|-------------------|---------------------------------------------------|
| 0                  | 0                 | 0                 | Setting prohibited (Initial value)                |
| 0                  | 0                 | 1                 | PHSEG2 = 2 time quanta (conditionally prohibited) |
| 0                  | 1                 | 0                 | PHSEG2 = 3 time quanta                            |
| 0                  | 1                 | 1                 | PHSEG2 = 4 time quanta                            |
| 1                  | 0                 | 0                 | PHSEG2 = 5 time quanta                            |
| 1                  | 0                 | 1                 | PHSEG2 = 6 time quanta                            |
| 1                  | 1                 | 0                 | PHSEG2 = 7 time quanta                            |
| 1                  | 1                 | 1                 | PHSEG2 = 8 time quanta                            |

**Bits 7 and 6: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 5 and 4 - ReSynchronisation Jump Width (SJW[1:0] = BCR0[5:4]):** These bits set the synchronisation jump width.

| Bit 5:<br>SJW[1] | Bit 4:<br>SJW[0] | Description                                                 |
|------------------|------------------|-------------------------------------------------------------|
| 0                | 0                | Synchronisation Jump width = 1 time quantum (Initial value) |
| 0                | 1                | Synchronisation Jump width = 2 time quanta                  |
| 1                | 0                | Synchronisation Jump width = 3 time quanta                  |

- Requirements of Bit Configuration Register

**SYNC\_SEG:** Segment for establishing synchronisation of nodes on the CAN bus. (Normal bit edge transitions occur in this segment.)

**PRSEG:** Segment for compensating for physical delay between networks.

**PHSEG1:** Buffer segment for correcting phase drift (positive). (This segment is extended when synchronisation (resynchronisation) is established.)

**PHSEG2:** Buffer segment for correcting phase drift (negative). (This segment is shortened when synchronisation (resynchronisation) is established.)

**TSEG1:** TSG1 + 1

TSEG2: TSG2 + 1

The RCAN-TL1 Bit Rate Calculation is:

$$\text{Bit Rate} = \frac{f_{\text{clk}}}{2 \times (\text{BRP} + 1) \times (\text{TSEG1} + \text{TSEG2} + 1)}$$

Where BRP is given by the register value and TSEG1 and TSEG2 are derived values from TSG1 and TSG2 register values. The '+1' in the above formula is for the Sync-Seg which duration is 1 time quanta.

$$f_{\text{CLK}} = \text{Peripheral Clock}$$

#### BCR Setting Constraints

$$\text{TSEG1}_{\text{min}} > \text{TSEG2} \geq \text{SJW}_{\text{max}} \quad (\text{SJW} = 1 \text{ to } 4)$$

$$8 \leq \text{TSEG1} + \text{TSEG2} + 1 \leq 25 \text{ time quanta} \quad (\text{TSEG1} + \text{TSEG2} + 1 = 7 \text{ is not allowed})$$

$$\text{TSEG2} \geq 2$$

These constraints allow the setting range shown in the table below for TSEG1 and TSEG2 in the Bit Configuration Register. The number in the table shows possible setting of SJW. "No" shows that there is no allowed combination of TSEG1 and TSEG2.

|      |       | 001 | 010 | 011 | 100 | 101 | 110 | 111 | TSG2  |
|------|-------|-----|-----|-----|-----|-----|-----|-----|-------|
|      |       | 2   | 3   | 4   | 5   | 6   | 7   | 8   | TSEG2 |
| TSG1 | TSEG1 |     |     |     |     |     |     |     |       |
| 0011 | 4     | No  | 1-3 | No  | No  | No  | No  | No  |       |
| 0100 | 5     | 1-2 | 1-3 | 1-4 | No  | No  | No  | No  |       |
| 0101 | 6     | 1-2 | 1-3 | 1-4 | 1-4 | No  | No  | No  |       |
| 0110 | 7     | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | No  | No  |       |
| 0111 | 8     | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | No  |       |
| 1000 | 9     | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1001 | 10    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1010 | 11    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1011 | 12    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1100 | 13    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1101 | 14    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1110 | 15    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1111 | 16    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |

**Example 1:** For a bit rate of 500 kbps when the fclk frequency is 32 MHz, satisfy the following conditions: BRP = 3, TSEG1 = 11, TSEG2 = 4. Write H'A300 to BCR1 and H'0001 to BCR0.

**Example 2:** For a bit rate of 500 kbps when the fclk frequency is 20 MHz, satisfy the following conditions: BRP = 1, TSEG1 = 6, TSEG2 = 3. Write H'5200 to BCR1 and H'0001 to BCR0.

#### (4) Interrupt Request Register (IRR)

The interrupt register (IRR) is a 16-bit read/write-clearable register containing status flags for the various interrupt sources.

- IRR (Address = H'008)

**Bit 15 — Timer Compare Match Interrupt 1 (IRR15):** Indicates that a Compare-Match condition occurred to the Timer Compare Match Register 1 (TCMR1). When the value set in the TCMR1 matches to Cycle Time (TCMR1 = CYCTR), this bit is set.

| Bit 15: IRR15 | Description                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------|
| 0             | Timer Compare Match has not occurred to the TCMR1 (Initial value)<br>[Clearing condition] Writing 1              |
| 1             | Timer Compare Match has occurred to the TCMR1<br>[Setting condition] TCMR1 matches to Cycle Time (TCMR1 = CYCTR) |

|   |                                                                                                                  |
|---|------------------------------------------------------------------------------------------------------------------|
| 0 | Timer Compare Match has not occurred to the TCMR1 (Initial value)<br>[Clearing condition] Writing 1              |
| 1 | Timer Compare Match has occurred to the TCMR1<br>[Setting condition] TCMR1 matches to Cycle Time (TCMR1 = CYCTR) |

**Bit 14 — Timer Compare Match Interrupt 0 (IRR14):** Indicates that a Compare-Match condition occurred to the Timer Compare Match Register 0 (TCMR0). When the value set in the TCMR0 matches to Local Time (TCMR0 = TCNTR), this bit is set.

| Bit 14: IRR14 | Description                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------|
| 0             | Timer Compare Match has not occurred to the TCMR0 (Initial value)<br>[Clearing condition] Writing 1                   |
| 1             | Timer Compare Match has occurred to the TCMR0<br>[Setting condition] TCMR0 matches to the Timer value (TCMR0 = TCNTR) |

|   |                                                                                                                       |
|---|-----------------------------------------------------------------------------------------------------------------------|
| 0 | Timer Compare Match has not occurred to the TCMR0 (Initial value)<br>[Clearing condition] Writing 1                   |
| 1 | Timer Compare Match has occurred to the TCMR0<br>[Setting condition] TCMR0 matches to the Timer value (TCMR0 = TCNTR) |

**Bit 13 - Timer Overrun Interrupt/Next\_is\_Gap Reception Interrupt/Message Error Interrupt (IRR13):** This interrupt assumes a different meaning depending on the RCAN-TL1 mode. It indicates that:

- The Timer (TCNTR) has overrun when RCAN-TL1 is working in event-trigger mode (including test modes)

- Time reference message with Next\_is\_Gap set has been received when working in time-trigger mode. Please note that when a Next\_is\_Gap is received the application is responsible to stop all transmission at the end of the current basic cycle (including test modes)
- Message error has occurred when in test mode. Note: If a Message Overload condition occurs when in Test Mode, then this bit will not be set.

| Bit 13: IRR13 | Description                                                                                                                                                                                                                                                                                                 |

| 1             | <p>[Setting condition]</p> <p>Timer (TCNTR) has overrun and changed from H'FFFF to H'0000 in event-trigger mode (including test modes)</p> <p>Time reference message with Next_is_Gap has been received in time-trigger mode (including test modes)</p> <p>Message error has occurred in test mode</p>      |

**Bit 12 – Bus activity while in sleep mode (IRR12):** IRR12 indicates that a CAN bus activity is present. While the RCAN-TL1 is in sleep mode and a dominant bit is detected on the CAN bus, this bit is set. This interrupt is cleared by writing a '1' to this bit position. Writing a '0' has no effect. If auto wakeup is not used and this interrupt is not requested it needs to be disabled by the related interrupt mask register. If auto wake up is not used and this interrupt is requested it should be cleared only after recovering from sleep mode. This is to avoid that a new falling edge of the reception line causes the interrupt to get set again.

Please note that the setting time of this interrupt is different from the clearing time of GSR4.

| Bit 12: IRR12 | Description                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|

| 1             | <p>CAN bus activity detected in RCAN-TL1 sleep mode</p> <p>[Setting condition]</p> <p>Dominant bit level detection on the Rx line while in sleep mode</p> |

**Bit 11 — Timer Compare Match Interrupt 2 (IRR11):** Indicates that a Compare-Match condition occurred to the Timer Compare Match Register 2 (TCMR2). When the value set in the TCMR2 matches to Cycle Time (TCMR2 = CYCTR), this bit is set.

| Bit 11: IRR11 | Description                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------|
| 0             | Timer Compare Match has not occurred to the TCMR2 (initial value)<br>[Clearing condition] Writing 1              |
| 1             | Timer Compare Match has occurred to the TCMR2<br>[Setting condition] TCMR2 matches to Cycle Time (TCMR2 = CYCTR) |

**Bit 10 — Start of new system matrix Interrupt (IRR10):** Indicates that a new system matrix is starting.

When CCR = 0, this bit is set at the successful completion of reception/transmission of time reference message. Please note that when CMAX = 0 this interrupt is set at every basic cycle.

| Bit 10: IRR10 | Description                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | A new system matrix is not starting (initial value)<br>[Clearing condition] Writing 1                                                                           |
| 1             | Cycle counter reached zero.<br>[Setting condition]<br>Reception/transmission of time reference message is successfully completed when CMAX!= 3'b111 and CCR = 0 |

**Bit 9 – Message Overrun/Overwrite Interrupt Flag (IRR9):** Flag indicating that a message has been received but the existing message in the matching Mailbox has not been read as the corresponding RXPR or RFPR is already set to '1' and not yet cleared by the CPU. The received message is either abandoned (overrun) or overwritten dependant upon the NMC (New Message Control) bit. This bit is cleared when all bit in UMSR (Unread Message Status Register) are cleared (by writing '1') or by setting MBIMR (MailBox interrupt Mast Register) for all UMSR flag set. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit position has no effect.

| Bit 9: IRR9 | Description                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | No pending notification of message overrun/overwrite<br>[Clearing condition]<br>Clearing of all bit in UMSR/setting MBIMR for all UMSR set (initial value)                                               |
| 1           | A receive message has been discarded due to overrun condition or a message has been overwritten<br>[Setting condition]<br>Message is received while the corresponding RXPR and/or RFPR = 1 and MBIMR = 0 |

**Bit 8 - Mailbox Empty Interrupt Flag (IRR8):** This bit is set when one of the messages set for transmission has been successfully sent (corresponding TXACK flag is set) or has been successfully aborted (corresponding ABACK flag is set). In Event Triggered mode the related TXPR is also cleared and this mailbox is now ready to accept a new message data for the next transmission. In Time Trigger mode TXPR for the Mailboxes from 30 to 24 is not cleared after a successful transmission in order to keep transmitting at each programmed basic cycle. In effect, this bit is set by an OR'ed signal of the TXACK and ABACK bits not masked by the corresponding MBIMR flag. Therefore, this bit is automatically cleared when all the TXACK and ABACK bits are cleared. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit position has no effect.

| Bit 8: IRR8 | Description                                                                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Messages set for transmission or transmission cancellation request NOT progressed. (Initial value)<br>[Clearing Condition]<br>All the TXACK and ABACK bits are cleared/setting MBIMR for all TXACK and ABACK set                                      |
| 1           | Message has been transmitted or aborted, and new message can be stored (in TT mode Mailbox 24 to 30 can be programmed with a new message only in case of abortion)<br>[Setting condition]<br>When a TXACK or ABACK bit is set (if related MBIMR = 0). |

**Bit 7 - Overload Frame (IRR7):** Flag indicating that the RCAN-TL1 has detected a condition that should initiate the transmission of an overload frame. Note that in the condition of transmission being prevented, such as listen only mode, an Overload Frame will NOT be transmitted, but IRR7 will still be set. IRR7 remains asserted until reset by writing a '1' to this bit position - writing a '0' has no effect.

| Bit 7: IRR7 | Description                                      |
|-------------|--------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)   |
| 1           | [Setting conditions] Overload condition detected |

**Bit 6 - Bus Off Interrupt Flag (IRR6):** This bit is set when RCAN-TL1 enters the Bus-off state or when RCAN-TL1 leaves Bus-off and returns to Error-Active. The cause therefore is the existing condition  $TEC \geq 256$  at the node or the end of the Bus-off recovery sequence (128X11 consecutive recessive bits) or the transition from Bus Off to Halt (automatic or manual). This bit remains set even if the RCAN-TL1 node leaves the bus-off condition, and needs to be explicitly cleared by S/W. The S/W is expected to read the GSR0 to judge whether RCAN-TL1 is in the bus-off or error active status. It is cleared by writing a '1' to this bit position even if the node is still bus-off. Writing a '0' has no effect.

| Bit 6: IRR6 | Description                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)                                                                                                                                                                                       |
| 1           | Enter Bus off state caused by transmit error or Error Active state returning from Bus-off<br>[Setting condition]<br>When $TEC \geq 256$ or End of Bus-off after 128X11 consecutive recessive bits or transition from Bus Off to Halt |

**Bit 5 - Error Passive Interrupt Flag (IRR5):** Interrupt flag indicating the error passive state caused by the transmit or receive error counter or by Error Passive forced by test mode. This bit is reset by writing a '1' to this bit position, writing a '0' has no effect. If this bit is cleared the node may still be error passive. Please note that the SW needs to check GSR0 and GSR5 to judge whether RCAN-TL1 is in Error Passive or Bus Off status.

| Bit 5: IRR5 | Description                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)                                                                                                          |
| 1           | Error passive state caused by transmit/receive error<br>[Setting condition]<br>When $TEC \geq 128$ or $REC \geq 128$ or Error Passive test mode is used |

**Bit 4 - Receive Error Counter Warning Interrupt Flag (IRR4):** This bit becomes set if the receive error counter (REC) reaches a value greater than 95 when RCAN-TL1 is not in the Bus Off status. The interrupt is reset by writing a '1' to this bit position, writing '0' has no effect.

| Bit 4: IRR4 | Description                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)                                                                       |
| 1           | Error warning state caused by receive error<br>[Setting condition] When $REC \geq 96$ and RCAN-TL1 is not in Bus Off |

**Bit 3 - Transmit Error Counter Warning Interrupt Flag (IRR3):** This bit becomes set if the transmit error counter (TEC) reaches a value greater than 95. The interrupt is reset by writing a '1' to this bit position, writing '0' has no effect.

| Bit 3: IRR3 | Description                                                                            |
|-------------|----------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)                                         |
| 1           | Error warning state caused by transmit error<br>[Setting condition] When $TEC \geq 96$ |

**Bit 2 - Remote Frame Receive Interrupt Flag (IRR2):** Flag indicating that a remote frame has been received in a mailbox. This bit is set if at least one receive mailbox, with related MBIMR not set, contains a remote frame transmission request. This bit is automatically cleared when all bits in the Remote Frame Receive Pending Register (RFPR), are cleared. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit has no effect.

| Bit 2: IRR2 | Description                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Clearing of all bits in RFPR (Initial value)                                                              |
| 1           | At least one remote request is pending<br>[Setting condition]<br>When remote frame is received and the corresponding MBIMR = 0 |

**Bit 1 - Data Frame Received Interrupt Flag (IRR1):** IRR1 indicates that there are pending Data Frames received. If this bit is set at least one receive mailbox contains a pending message. This bit is cleared when all bits in the Data Frame Receive Pending Register (RXPR) are cleared, i.e. there is no pending message in any receiving mailbox. It is in effect a logical OR of the RXPR flags from each configured receive mailbox with related MBIMR not set. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit has no effect.

| Bit 1: IRR1 | Description                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Clearing of all bits in RXPR (Initial value)                                                      |
| 1           | Data frame received and stored in Mailbox<br>[Setting condition] When data is received and the corresponding MBIMR = 0 |

**Bit 0 – Reset/Halt/Sleep Interrupt Flag (IRR0):** This flag can get set for three different reasons. It can indicate that:

1. Reset mode has been entered after a SW (MCR0) or HW reset
2. Halt mode has been entered after a Halt request (MCR1)
3. Sleep mode has been entered after a sleep request (MCR5) has been made while in Halt mode.

The GSR may be read after this bit is set to determine which state RCAN-TL1 is in.

**Important:** When a Sleep mode request needs to be made, the Halt mode must be used beforehand. Please refer to the MCR5 description and Figure 19.15 Halt Mode/Sleep Mode.

IRR0 is set by the transition from "0" to "1" of GSR3 or GSR4 or by transition from Halt mode to Sleep mode. So, IRR0 is not set if RCAN-TL1 enters Halt mode again right after exiting from Halt mode, without GSR4 being cleared. Similarly, IRR0 is not set by direct transition from Sleep mode to Halt Request. At the transition from Halt/Sleep mode to Transition/Reception, clearing GSR4 needs (one-bit time - TSEG2) to (one-bit time \* 2 - TSEG2).

In the case of Reset mode, IRR0 is set, however, the interrupt to the CPU is not asserted since IMR0 is automatically set by initialisation.

| Bit 0: IRR0 | Description                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1                                                                                                                                                                                                                               |
| 1           | Transition to S/W reset mode or transition to halt mode or transition to sleep mode (Initial value)<br>[Setting condition]<br>When reset/halt/sleep transition is completed after a reset (MCR0 or HW) or Halt mode (MCR1) or Sleep mode (MCR5) is requested |

(5)    **Interrupt Mask Register (IMR)**

The interrupt mask register is a 16 bit register that protects all corresponding interrupts in the Interrupt Request Register (IRR) from generating an output signal on the IRQ. An interrupt request is masked if the corresponding bit position is set to ‘1’. This register can be read or written at any time. The IMR directly controls the generation of IRQ, but does not prevent the setting of the corresponding bit in the IRR.

- IMR (Address = H'00A)

|                |       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|----------------|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| Bit:           | 15    | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|                | IMR15 | IMR14 | IMR13 | IMR12 | IMR11 | IMR10 | IMR9 | IMR8 | IMR7 | IMR6 | IMR5 | IMR4 | IMR3 | IMR2 | IMR1 | IMR0 |
| Initial value: | 1     | 1     | 1     | 1     | 1     | 1     | 1    | 1    | 1    | 1    | 1    | 1    | 1    | 1    | 1    | 1    |
| R/W:           | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |

**Bits 15 to 0:** Maskable interrupt sources corresponding to IRR[15:0] respectively. When a bit is set, the interrupt signal is not generated, although setting the corresponding IRR bit is still performed.

| Bit[15:0]: IMRn | Description                                                                 |
|-----------------|-----------------------------------------------------------------------------|
| 0               | Corresponding IRR is not masked (IRQ is generated for interrupt conditions) |
| 1               | Corresponding interrupt of IRR is masked (Initial value)                    |

(6)    **Transmit Error Counter (TEC) and Receive Error Counter (REC)**

The Transmit Error Counter (TEC) and Receive Error Counter (REC) is a 16-bit read/(write) register that functions as a counter indicating the number of transmit/receive message errors on the CAN Interface. The count value is stipulated in the CAN protocol specification Refs. [1], [2], [3] and [4]. When not in (Write Error Counter) test mode this register is read only, and can only be modified by the CAN Interface. This register can be cleared by a Reset request (MCR0) or entering to bus off.

In Write Error Counter test mode (i.e. TST[2:0] = 3'b100), it is possible to write to this register. The same value can only be written to TEC/REC, and the value written into TEC is set to TEC and REC. When writing to this register, RCAN-TL1 needs to be put into Halt Mode. This feature is only intended for test purposes.

- TEC/REC (Address = H'00C)

|                |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Bit:           | 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|                | TEC7 | TEC6 | TEC5 | TEC4 | TEC3 | TEC2 | TEC1 | TEC0 | REC7 | REC6 | REC5 | REC4 | REC3 | REC2 | REC1 | REC0 |
| Initial value: | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |
| R/W:           | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* |

Note: \* It is only possible to write the value in test mode when TST[2:0] in MCR is 3'b100.  
REC is incremented during Bus Off to count the recurrences of 11 recessive bits as requested by the Bus Off recovery sequence.

### 19.3.4 RCAN-TL1 Mailbox Registers

The following sections describe RCAN-TL1 Mailbox registers that control/flag individual Mailboxes. The address is mapped as follows.

**Important:** LongWord access is carried out as two consecutive Word accesses.

| 32-Mailboxes version              |         |        |                    |
|-----------------------------------|---------|--------|--------------------|
| Description                       | Address | Name   | Access Size (bits) |
| Transmit Pending 1                | 020     | TXPR1  | LW                 |
| Transmit Pending 0                | 022     | TXPR0  | —                  |
|                                   | 024     |        |                    |
|                                   | 026     |        |                    |
| Transmit Cancel 1                 | 028     | TXCR1  | Word/LW            |
| Transmit Cancel 0                 | 02A     | TXCR0  | Word               |
|                                   | 02C     |        |                    |
|                                   | 02E     |        |                    |
| Transmit Acknowledge 1            | 030     | TXACK1 | Word/LW            |
| Transmit Acknowledge 0            | 032     | TXACK0 | Word               |
|                                   | 034     |        |                    |
|                                   | 036     |        |                    |
| Abort Acknowledge 1               | 038     | ABACK1 | Word/LW            |
| Abort Acknowledge 0               | 03A     | ABACK0 | Word               |
|                                   | 03C     |        |                    |
|                                   | 03E     |        |                    |
| Data Frame Receive Pending 1      | 040     | RXPR1  | Word/LW            |
| Data Frame Receive Pending 0      | 042     | RXPR0  | Word               |
|                                   | 044     |        |                    |

Figure 19.11 RCAN-TL1 Mailbox registers

## (1) Transmit Pending Register (TXPR1, TXPR0)

The concatenation of TXPR1 and TXPR0 is a 32-bit register that contains any transmit pending flags for the CAN module. In the case of 16-bit bus interface, Long Word access is carried out as two consecutive word accesses.

### <Longword Write Operation>

### <Longword Read Operation>

The TXPR1 controls Mailbox-31 to Mailbox-16, and the TXPR0 controls Mailbox-15 to Mailbox-1. The CPU may set the TXPR bits to affect any message being considered for transmission by writing a '1' to the corresponding bit location. Writing a '0' has no effect, and TXPR cannot be cleared by writing a '0' and must be cleared by setting the corresponding TXCR bits. TXPR may be read by the CPU to determine which, if any, transmissions are pending or in progress. In effect there is a transmit pending bit for all Mailboxes except for the Mailbox-0. Writing a '1' to a bit location when the mailbox is not configured to transmit is not allowed.

In Event Triggered Mode RCAN-TL1 will clear a transmit pending flag after successful transmission of its corresponding message or when a transmission abort is requested successfully from the TXCR. In Time Trigger Mode, TXPR for the Mailboxes from 30 to 24 is NOT cleared after a successful transmission, in order to keep transmitting at each programmed basic cycle. The TXPR flag is not cleared if the message is not transmitted due to the CAN node losing the arbitration process or due to errors on the CAN bus, and RCAN-TL1 automatically tries to transmit it again unless its DART bit (Disable Automatic Re-Transmission) is set in the Message-Control of the corresponding Mailbox. In such case (DART set), the transmission is cleared and notified through Mailbox Empty Interrupt Flag (IRR8) and the correspondent bit within the Abort Acknowledgement Register (ABACK).

If the status of the TXPR changes, the RCAN-TL1 shall ensure that in the identifier priority scheme (MCR2 = 0), the highest priority message is always presented for transmission in an intelligent way even under circumstances such as bus arbitration losses or errors on the CAN bus. Please refer to the Application Note for details.

When the RCAN-TL1 changes the state of any TXPR bit position to a '0', an empty slot interrupt (IRR8) may be generated. This indicates that either a successful or an aborted mailbox transmission has just been made. If a message transmission is successful it is signalled in the TXACK register, and if a message transmission abortion is successful it is signalled in the ABACK register. By checking these registers, the contents of the Message of the corresponding Mailbox may be modified to prepare for the next transmission.

• TXPR1

Note:    \*    It is possible only to write a ‘1’ for a Mailbox configured as transmitter.

**Bits 15 to 0** — Requests the corresponding Mailbox to transmit a CAN Frame. The bit 15 to 0 corresponds to Mailbox-31 to 16 respectively. When multiple bits are set, the order of the transmissions is governed by the MCR2 – CAN-ID or Mailbox number.

| Bit[15:0]: TXPR1 | Description                                                                                                                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | Transmit message idle state in corresponding mailbox (Initial value)<br>[Clearing Condition]<br>Completion of message transmission (for Event Triggered Messages) or message transmission abortion (automatically cleared) |
| 1                | Transmission request made for corresponding mailbox                                                                                                                                                                        |

• TXPR0

Note: \* It is possible only to write a ‘1’ for a Mailbox configured as transmitter.

**Bits 15 to 1** — Indicates that the corresponding Mailbox is requested to transmit a CAN Frame. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively. When multiple bits are set, the order of the transmissions is governed by the MCR2 – CAN-ID or Mailbox number.

| Bit[15:1]: TXPR0 | Description                                                                                                                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | Transmit message idle state in corresponding mailbox (Initial value)<br>[Clearing Condition]<br>Completion of message transmission (for Event Triggered Messages) or message transmission abortion (automatically cleared) |
| 1                | Transmission request made for corresponding mailbox                                                                                                                                                                        |

**Bit 0— Reserved:** This bit is always ‘0’ as this is a receive-only Mailbox. Writing a ‘1’ to this bit position has no effect. The returned value is ‘0’.

(2) Transmit Cancel Register (TXCR1, TXCR0)

The TXCR1 and TXCR0 are 16-bit read/conditionally-write registers. The TXCR1 controls Mailbox-31 to Mailbox-16, and the TXCR0 controls Mailbox-15 to Mailbox-1. This register is used by the CPU to request the pending transmission requests in the TXPR to be cancelled. To clear the corresponding bit in the TXPR the CPU must write a ‘1’ to the bit position in the TXCR. Writing a ‘0’ has no effect.

When an abort has succeeded the CAN controller clears the corresponding TXPR + TXCR bits, and sets the corresponding ABACK bit. However, once a Mailbox has started a transmission, it cannot be cancelled by this bit. In such a case, if the transmission finishes in success, the CAN controller clears the corresponding TXPR + TXCR bit, and sets the corresponding TXACK bit, however, if the transmission fails due to a bus arbitration loss or an error on the bus, the CAN controller clears the corresponding TXPR + TXCR bit, and sets the corresponding ABACK bit. If an attempt is made by the CPU to clear a mailbox transmission that is not transmit-pending it has no effect. In this case the CPU will be not able at all to set the TXCR flag.

• TXCR1

Note: \* Only writing a ‘1’ to a Mailbox that is requested for transmission and is configured as transmit.

**Bits 15 to 0** — Requests the corresponding Mailbox, that is in the queue for transmission, to cancel its transmission. The bit 15 to 0 corresponds to Mailbox-31 to 16 (and TXPR1[15:0]) respectively.

| Bit[15:0]:TXCR1 | Description                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0               | Transmit message cancellation idle state in corresponding mailbox (Initial value)<br>[Clearing Condition]<br>Completion of transmit message cancellation (automatically cleared) |
| 1               | Transmission cancellation request made for corresponding mailbox                                                                                                                 |

• TXCR0

Note: \* Only writing a ‘1’ to a Mailbox that is requested for transmission and is configured as transmit.

**Bits 15 to 1** — Requests the corresponding Mailbox, that is in the queue for transmission, to cancel its transmission. The bit 15 to 1 corresponds to Mailbox-15 to 1 (and TXPR0[15:1]) respectively.

| Bit[15:1]: TXCR0 | Description                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | Transmit message cancellation idle state in corresponding mailbox (Initial value)<br>[Clearing Condition]<br>Completion of transmit message cancellation (automatically cleared) |
| 1                | Transmission cancellation request made for corresponding mailbox                                                                                                                 |

**Bit 0** — This bit is always ‘0’ as this is a receive-only mailbox. Writing a ‘1’ to this bit position has no effect and always read back as a ‘0’.

(3) Transmit Acknowledge Register (TXACK1, TXACK0)

The TXACK1 and TXACK0 are 16-bit read/conditionally-write registers. These registers are used to signal to the CPU that a mailbox transmission has been successfully made. When a transmission has succeeded the RCAN-TL1 sets the corresponding bit in the TXACK register. The CPU may clear a TXACK bit by writing a ‘1’ to the corresponding bit location. Writing a ‘0’ has no effect.

• TXACK1

Note: \* Only when writing a ‘1’ to clear.

**Bits 15 to 0** — Notifies that the requested transmission of the corresponding Mailbox has been finished successfully. The bit 15 to 0 corresponds to Mailbox-31 to 16 respectively.

**Bit[15:0]:TXACK1 Description**

|   |                                                                                                                                                                          |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | [Clearing Condition] Writing '1' (Initial value)                                                                                                                         |
| 1 | Corresponding Mailbox has successfully transmitted message (Data or Remote Frame)<br>[Setting Condition]<br>Completion of message transmission for corresponding mailbox |

• TXACK0

|                |              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |   |
|----------------|--------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|---|
| Bit:           | 15           | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0 |
|                | TXACK0[15:1] |      |      |      |      |      |      |      |      |      |      |      |      |      |      | - |
| Initial value: | 0            | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0 |
| R/W:           | R/W*         | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | - |

Note: \* Only when writing a '1' to clear.

**Bits 15 to 1** — Notifies that the requested transmission of the corresponding Mailbox has been finished successfully. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively.

**Bit[15:1]:TXACK0 Description**

|   |                                                                                                                                                                          |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | [Clearing Condition] Writing '1' (Initial value)                                                                                                                         |
| 1 | Corresponding Mailbox has successfully transmitted message (Data or Remote Frame)<br>[Setting Condition]<br>Completion of message transmission for corresponding mailbox |

**Bit 0** — This bit is always '0' as this is a receive-only mailbox. Writing a '1' to this bit position has no effect and always read back as a '0'.

(4) Abort Acknowledge Register (ABACK1, ABACK0)

The ABACK1 and ABACK0 are 16-bit read/conditionally-write registers. These registers are used to signal to the CPU that a mailbox transmission has been aborted as per its request. When an abort has succeeded the RCAN-TL1 sets the corresponding bit in the ABACK register. The CPU may clear the Abort Acknowledge bit by writing a ‘1’ to the corresponding bit location. Writing a ‘0’ has no effect. An ABACK bit position is set by the RCAN-TL1 to acknowledge that a TXPR bit has been cleared by the corresponding TXCR bit.

• ABACK1

Note: \* Only when writing a ‘1’ to clear.

**Bits 15 to 0** — Notifies that the requested transmission cancellation of the corresponding Mailbox has been performed successfully. The bit 15 to 0 corresponds to Mailbox-31 to 16 respectively.

| Bit[15:0]:ABACK1 | Description                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (Initial value)                                                                                                                               |
| 1                | Corresponding Mailbox has cancelled transmission of message (Data or Remote Frame)<br>[Setting Condition]<br>Completion of transmission cancellation for corresponding mailbox |

• ABACK0

Note: \* Only when writing a ‘1’ to clear.

**Bits 15 to 1** — Notifies that the requested transmission cancellation of the corresponding Mailbox has been performed successfully. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively.

| Bit[15:1]:ABACK0 | Description                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing '1' (Initial value)                                                                                                                               |
| 1                | Corresponding Mailbox has cancelled transmission of message (Data or Remote Frame)<br>[Setting Condition]<br>Completion of transmission cancellation for corresponding mailbox |

**Bit 0** — This bit is always ‘0’ as this is a receive-only mailbox. Writing a ‘1’ to this bit position has no effect and always read back as a ‘0’.

**(5)    Data Frame Receive Pending Register (RXPR1, RXPR0)**

The RXPR1 and RXPR0 are 16-bit read/conditionally-write registers. The RXPR is a register that contains the received Data Frames pending flags associated with the configured Receive Mailboxes. When a CAN Data Frame is successfully stored in a receive mailbox the corresponding bit is set in the RXPR. The bit may be cleared by writing a ‘1’ to the corresponding bit position. Writing a ‘0’ has no effect. However, the bit may only be set if the mailbox is configured by its MBC (Mailbox Configuration) to receive Data Frames. When a RXPR bit is set, it also sets IRR1 (Data Frame Received Interrupt Flag) if its MBIMR (Mailbox Interrupt Mask Register) is not set, and the interrupt signal is generated if IMR1 is not set. Please note that these bits are only set by receiving Data Frames and not by receiving Remote frames.

•    RXPR1

Note : \*    Only when writing a ‘1’ to clear.

**Bits 15 to 0** — Configurable receive mailbox locations corresponding to each mailbox position from 31 to 16 respectively.

| Bit[15:0]: RXPR1 | Description                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing '1' (Initial value)                                                                                    |
| 1                | Corresponding Mailbox received a CAN Data Frame<br>[Setting Condition]<br>Completion of Data Frame receive on corresponding mailbox |

• RXPR0

Note: \* Only when writing a ‘1’ to clear.

**Bits 15 to 0** — Configurable receive mailbox locations corresponding to each mailbox position from 15 to 0 respectively.

| Bit[15:0]: RXPR0 | Description                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (Initial value)                                                                                    |
| 1                | Corresponding Mailbox received a CAN Data Frame<br>[Setting Condition]<br>Completion of Data Frame receive on corresponding mailbox |

**Bits 15 to 0** — Remote Request pending flags for mailboxes 15 to 0 respectively.

| Bit[15:0]: RFPR0 | Description                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (Initial value)                                                                                  |
| 1                | Corresponding Mailbox received Remote Frame<br>[Setting Condition]<br>Completion of remote frame receive in corresponding mailbox |

**(7) Mailbox Interrupt Mask Register (MBIMR)**

The MBIMR1 and MBIMR0 are 16-bit read/write registers. The MBIMR only prevents the setting of IRR related to the Mailbox activities, that are IRR[1] – Data Frame Received Interrupt, IRR[2] – Remote Frame Receive Interrupt, IRR[8] – Mailbox Empty Interrupt, and IRR[9] – Message OverRun/OverWrite Interrupt. If a mailbox is configured as receive, a mask at the corresponding bit position prevents the generation of a receive interrupt (IRR[1] and IRR[2] and IRR[9]) but does not prevent the setting of the corresponding bit in the RXPR or RFPR or UMSR. Similarly when a mailbox has been configured for transmission, a mask prevents the generation of an Interrupt signal and setting of an Mailbox Empty Interrupt due to successful transmission or abortion of transmission (IRR[8]), however, it does not prevent the RCAN-TL1 from clearing the corresponding TXPR/TXCR bit + setting the TXACK bit for successful transmission, and it does not prevent the RCAN-TL1 from clearing the corresponding TXPR/TXCR bit + setting the ABACK bit for abortion of the transmission.

A mask is set by writing a ‘1’ to the corresponding bit position for the mailbox activity to be masked. At reset all mailbox interrupts are masked.

- MBIMR1

**Bits 15 to 0** — Enable or disable interrupt requests from individual Mailbox-31 to Mailbox-16 respectively.

| Bit[15:0]: MBIMR1 | Description                                                         |
|-------------------|---------------------------------------------------------------------|
| 0                 | Interrupt Request from IRR1/IRR2/IRR8/IRR9 enabled                  |
| 1                 | Interrupt Request from IRR1/IRR2/IRR8/IRR9 disabled (initial value) |

• MBIMR0

**Bits 15 to 0** — Enable or disable interrupt requests from individual Mailbox-15 to Mailbox-0 respectively.

| Bit[15:0]: MBIMR0 | Description                                                         |
|-------------------|---------------------------------------------------------------------|
| 0                 | Interrupt Request from IRR1/IRR2/IRR8/IRR9 enabled                  |
| 1                 | Interrupt Request from IRR1/IRR2/IRR8/IRR9 disabled (initial value) |

(8) Unread Message Status Register (UMSR)

This register is a 32-bit read/conditionally write register and it records the mailboxes whose contents have not been accessed by the CPU prior to a new message being received. If the CPU has not cleared the corresponding bit in the RXPR or RFPR when a new message for that mailbox is received, the corresponding UMSR bit is set to ‘1’. This bit may be cleared by writing a ‘1’ to the corresponding bit location in the UMSR. Writing a ‘0’ has no effect.

If a mailbox is configured as transmit box, the corresponding UMSR will not be set.

• UMSR1

Note: \* Only when writing a ‘1’ to clear.

**Bits 15 to 0** — Indicate that an unread received message has been overwritten or overrun condition has occurred for Mailboxes 31 to 16.

| Bit[15:0]: UMSR1 | Description                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (initial value)                                                                                                                     |
| 1                | Unread received message is overwritten by a new message or overrun condition<br>[Setting Condition]<br>When a new message is received before RXPR or RFPR is cleared |

• UMSR0

Note: \* Only when writing a ‘1’ to clear.

**Bits 15 to 0** — Indicate that an unread received message has been overwritten or overrun condition has occurred for Mailboxes 15 to 0.

| Bit[15:0]: UMSR0 | Description                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (initial value)                                                                                                                     |
| 1                | Unread received message is overwritten by a new message or overrun condition<br>[Setting Condition]<br>When a new message is received before RXPR or RFPR is cleared |

### 19.3.5 Timer Registers

The Timer is 16 bits and supports several source clocks. A pre-scale counter can be used to reduce the speed of the clock. It also supports three Compare Match Registers (TCMR2, TCMR1, TCMR0). The address map is as follows.

**Important:** These registers can only be accessed in Word size (16-bit).

| Description                             | Address | Name     | Access Size (bits) |
|-----------------------------------------|---------|----------|--------------------|
| Timer Trigger Control Register 0        | 080     | TTCR0    | Word (16)          |
| Cycle Maximum/Tx-Enable Window Register | 084     | CMAX_TEW | Word (16)          |
| Reference Trigger Offset Register       | 086     | RFTROFF  | Word (16)          |
| Timer Status Register                   | 088     | TSR      | Word (16)          |
| Cycle Counter Register                  | 08A     | CCR      | Word (16)          |
| Timer Counter Register                  | 08C     | TCNTR    | Word (16)          |
| Cycle Time Register                     | 090     | CYCTR    | Word (16)          |
| Reference Mark Register                 | 094     | RFMK     | Word (16)          |
| Timer Compare Match Register 0          | 098     | TCMR0    | Word (16)          |
| Timer Compare Match Register 1          | 09C     | TCMR1    | Word (16)          |
| Timer Compare Match Register 2          | 0A0     | TCMR2    | Word (16)          |
| Tx-Trigger Time Selection Register      | 0A4     | TTTSEL   | Word (16)          |

**Figure 19.12 RCAN-TL1 Timer registers**

#### (1) Time Trigger Control Register0 (TTCR0)

The Time Trigger Control Register0 is a 16-bit read/write register and provides functions to control the operation of the Timer. When operating in Time Trigger Mode, please refer to section 19.4.3 (1), Time Triggered Transmission.

- TTCR0 (Address = H'080)

|                |       |       |       |       |       |       |   |   |   |      |       |       |       |       |       |       |
|----------------|-------|-------|-------|-------|-------|-------|---|---|---|------|-------|-------|-------|-------|-------|-------|
| Bit:           | 15    | 14    | 13    | 12    | 11    | 10    | 9 | 8 | 7 | 6    | 5     | 4     | 3     | 2     | 1     | 0     |
|                | TCR15 | TCR14 | TCR13 | TCR12 | TCR11 | TCR10 | - | - | - | TCR6 | TPSC5 | TPSC4 | TPSC3 | TPSC2 | TPSC1 | TPSC0 |
| Initial value: | 0     | 0     | 0     | 0     | 0     | 0     | 0 | 0 | 0 | 0    | 0     | 0     | 0     | 0     | 0     | 0     |
| R/W:           | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R | R | R | R/W  | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |

**Bit 15 — Enable Timer:** When this bit is set, the timer TCNTR is running. When this bit is cleared, TCNTR and CCR are cleared.

| Bit15: TTCR0 15 | Description                                            |
|-----------------|--------------------------------------------------------|
| 0               | Timer and CCR are cleared and disabled (initial value) |
| 1               | Timer is running                                       |

**Bit 14 — TimeStamp value:** Specifies if the TimeStamp for transmission and reception in Mailboxes 15 to 0 must contain the Cycle Time (CYCTR) or the concatenation of CCR[5:0] + CYCTR[15:6]. This feature is very useful for time triggered transmission to monitor Rx\_Trigger.

This register does not affect the TimeStamp for Mailboxes 30 and 31.

| Bit14: TTCR0 14 | Description                                                                |
|-----------------|----------------------------------------------------------------------------|
| 0               | CYCTR[15:0] is used for the TimeStamp in Mailboxes 15 to 0 (initial value) |
| 1               | CCR[5:0] + CYCTR[15:6] is used for the TimeStamp in Mailboxes 15 to 0      |

**Bit 13 — Cancellation by TCMR2:** The messages in the transmission queue are cancelled by setting TXCR, when both this bit and bit12 are set and compare match occurs when RCAN-TL1 is not in the Halt status, causing the setting of all TXCR bits with the corresponding TXPR bits set.

| Bit13: TTCR0 13 | Description                                                     |
|-----------------|-----------------------------------------------------------------|
| 0               | Cancellation by TCMR2 compare match is disabled (initial value) |
| 1               | Cancellation by TCMR2 compare match is enabled                  |

**Bit 12 — TCMR2 compare match enable:** When this bit is set, IRR11 is set by TCMR2 compare match.

| Bit12 TTCR0 12 | Description                                            |
|----------------|--------------------------------------------------------|
| 0              | IRR11 isn't set by TCMR2 compare match (initial value) |
| 1              | IRR11 is set by TCMR2 compare match                    |

**Bit 11 — TCMR1 compare match enable:** When this bit is set, IRR15 is set by TCMR1 compare match.

| Bit11 TTCR0 11 | Description                                            |
|----------------|--------------------------------------------------------|
| 0              | IRR15 isn't set by TCMR1 compare match (initial value) |
| 1              | IRR15 is set by TCMR1 compare match                    |

**Bit 10 — TCMR0 compare match enable:** When this bit is set, IRR14 is set by TCMR0 compare match.

| Bit10 TTCR0 10 | Description                                            |
|----------------|--------------------------------------------------------|
| 0              | IRR14 isn't set by TCMR0 compare match (initial value) |
| 1              | IRR14 is set by TCMR0 compare match                    |

**Bits 9 to 7: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 6 — Timer Clear-Set Control by TCMR0:** Specifies if the Timer is to be cleared and set to H'0000 when the TCMR0 matches to the TCNTR. Please note that the TCMR0 is also capable to generate an interrupt signal to the CPU via IRR14.

**Note:** If RCAN-TL1 is working in TTCAN mode (CMAX isn't 3'b111), TTCR0 bit6 has to be '0' to avoid clearing Local Time.

| Bit6: TTCR0 6 | Description                                       |
|---------------|---------------------------------------------------|
| 0             | Timer is not cleared by the TCMR0 (initial value) |
| 1             | Timer is cleared by the TCMR0                     |

**Bits 5 to 0 — RCAN-TL1 Timer Prescaler (TPSC[5:0]):** This control field allows the timer source clock (4\*[RCAN-TL1 system clock]) to be divided before it is used for the timer. This function is available only in event-trigger mode. In time trigger mode (CMAX is not 3'b111), one nominal Bit Timing (= one bit length of CAN bus) is automatically chosen as source clock of TCNTR.

The following relationship exists between source clock period and the timer period.

| Bit[5:0]: TPSC[5:0] | Description                      |
|---------------------|----------------------------------|
| 0 0 0 0 0           | 1 X Source Clock (initial value) |
| 0 0 0 0 1           | 2 X Source Clock                 |
| 0 0 0 1 0           | 3 X Source Clock                 |
| 0 0 0 1 1           | 4 X Source Clock                 |
| 0 0 0 1 0 0         | 5 X Source Clock                 |
| .....               | .....                            |
| .....               | .....                            |
| 1 1 1 1 1 1         | 64 X Source Clock                |

(2) Cycle Maximum/Tx-Enable Window Register (CMAX\_TEW)

This register is a 16-bit read/write register. CMAX specifies the maximum value for the cycle counter (CCR) for TT Transmissions to set the number of basic cycles in the matrix system. When the Cycle Counter reaches the maximum value (CCR = CMAX), after a full basic cycle, it is cleared to zero and an interrupt is generated on IRR.10.

TEW specifies the width of Tx-Enable window.

- CMAX\_TEW (Address = H'084)

|                |    |    |    |    |    |           |     |     |   |   |   |   |          |     |     |     |
|----------------|----|----|----|----|----|-----------|-----|-----|---|---|---|---|----------|-----|-----|-----|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10        | 9   | 8   | 7 | 6 | 5 | 4 | 3        | 2   | 1   | 0   |
|                | -  | -  | -  | -  | -  | CMAX[2:0] |     |     | - | - | - | - | TEW[3:0] |     |     |     |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 1         | 1   | 1   | 0 | 0 | 0 | 0 | 0        | 0   | 0   | 0   |
| R/W:           | R  | R  | R  | R  | R  | R/W       | R/W | R/W | R | R | R | R | R/W      | R/W | R/W | R/W |

**Bits 15 to 11: Reserved.** The written value should always be ‘0’ and the returned value is ‘0’.

**Bits 10 to 8 — Cycle Count Maximum (CMAX):** Indicates the maximum number of CCR. The number of basic cycles available in the matrix cycle for Timer Triggered transmission is (Cycle Count Maximum + 1).

Unless CMAX = 3'b111, RCAN-TL1 is in time-trigger mode and time trigger function is available. If CMAX = 3'b111, RCAN-TL1 is in event-trigger mode.

| Bit[10:8]: CMAX[2:0] | Description                                                           |
|----------------------|-----------------------------------------------------------------------|
| 0 0 0                | Cycle Count Maximum = 0                                               |
| 0 0 1                | Cycle Count Maximum = 1                                               |
| 0 1 0                | Cycle Count Maximum = 3                                               |
| 0 1 1                | Cycle Count Maximum = 7                                               |
| 1 0 0                | Cycle Count Maximum = 15                                              |
| 1 0 1                | Cycle Count Maximum = 31                                              |
| 1 1 0                | Cycle Count Maximum = 63                                              |
| 1 1 1                | CCR is cleared and RCAN-TL1 is in event-trigger mode. (initial value) |

**Important:** Please set CMAX = 3'b111 when event-trigger mode is used.

**Bits 7 to 4: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 3 to 0 — Tx-Enable Window (TEW):** Indicates the width of Tx-Enable Window. TEW = H'00 shows the width is one nominal Bit Timing. All values from 0 to 15 are allowed to be set.

| Bit[3:0]: TEW[3:0] | Description                                       |
|--------------------|---------------------------------------------------|
| 0 0 0 0            | The width of Tx-Enable Window = 1 (initial value) |
| 0 0 0 1            | The width of Tx-Enable Window = 2                 |
| 0 0 1 0            | The width of Tx-Enable Window = 3                 |
| 0 0 1 1            | The width of Tx-Enable Window = 4                 |
| ....               | .....                                             |
| ....               | .....                                             |
| 1 1 1 1            | The width of Tx-Enable Window = 16                |

Note: The CAN core always needs a time between 1 to 2 bit timing to initiate transmission. The above values are not considering this accuracy.

### (3) Reference Trigger Offset Register (RFTROFF)

This is a 8-bit read/write register that affects Tx-Trigger Time (TTT) of Mailbox-30. The TTT of Mailbox-30 is compared with CYCTR after RFTROFF extended with sign is added to the TTT. However, the value of TTT is not modified. The offset value doesn't affect others except Mailbox-30.

- RFTROFF (Address = H'086)

|                |              |     |     |     |     |     |     |     |   |   |   |   |   |   |   |   |
|----------------|--------------|-----|-----|-----|-----|-----|-----|-----|---|---|---|---|---|---|---|---|
| Bit:           | 15           | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                | RFTROFF[7:0] |     |     |     |     |     |     |     | - | - | - | - | - | - | - | - |
| Initial value: | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R |

**Bits 15 to 8** — Indicate the value of Reference Trigger Offset.

**Bits 7 to 0: Reserved.** The written value should always be '0' and the returned value is '0'.

| Bit15 | Bit14 | Bit13 | Bit12 | Bit11 | Bit10 | Bit9 | Bit8 | Description                                |
|-------|-------|-------|-------|-------|-------|------|------|--------------------------------------------|
| 0     | 0     | 0     | 0     | 0     | 0     | 0    | 0    | Ref_trigger_offset = +0<br>(initial value) |
| 0     | 0     | 0     | 0     | 0     | 0     | 0    | 1    | Ref_trigger_offset = +1                    |

#### (4) Timer Status Register (TSR)

This register is a 16-bit read-only register, and allows the CPU to monitor the Timer Compare Match status and the Timer Overrun Status.

- TSR (Address = H'088)

|                |    |    |    |    |    |    |   |   |   |   |   |      |      |      |      |      |
|----------------|----|----|----|----|----|----|---|---|---|---|---|------|------|------|------|------|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4    | 3    | 2    | 1    | 0    |
|                | -  | -  | -  | -  | -  | -  | - | - | - | - | - | TSR4 | TSR3 | TSR2 | TSR1 | TSR0 |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0    | 0    | 0    | 0    | 0    |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R | R | R | R    | R    | R    | R    | R    |

**Bits 15 to 5: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 4 to 0 — RCAN-TL1 Timer Status (TSR[4:0]):** This read-only field allows the CPU to monitor the status of the Cycle Counter, the Timer and the Compare Match registers. Writing to this field has no effect.

**Bit 4 — Start of New System Matrix (TSR4):** Indicates that a new system matrix is starting. When CCR = 0, this bit is set at the successful completion of reception/transmission of time reference message.

| Bit4: TSR4 | Description                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | A new system matrix is not starting (initial value)<br>[Clearing condition] Writing '1' to IRR10 (Cycle Counter Overflow Interrupt)                                                                                                       |
| 1          | Cycle counter reached zero<br>[Setting condition]<br>When the Cycle Counter value changes from the maximum value (CMAX) to H'0. Reception/transmission of time reference message is successfully completed when CMAX!= 3'b111 and CCR = 0 |

**Bit 3 — Timer Compare Match Flag 2 (TSR3):** Indicates that a Compare-Match condition occurred to the Timer Compare Match Register 2 (TCMR2). When the value set in the TCMR2 matches to Cycle Time Register (TCMR2 = CYCTR), this bit is set if TTCR0 bit12 = 1. Please note that this bit is read-only and is cleared when IRR11 (Timer Compare Match Interrupt 2) is cleared.

| Bit3: TSR3 | Description                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | Timer Compare Match has not occurred to the TCMR2 (Initial value)<br>[Clearing condition] Writing '1' to IRR11 (Timer Compare Match Interrupt 1) |
| 1          | Timer Compare Match has occurred to the TCMR2<br>[Setting condition]<br>TCMR2 matches to Cycle Time (TCMR2 = CYCTR), if TTCR0 bit12 = 1.         |

**Bit 2 — Timer Compare Match Flag 1 (TSR2):** Indicates that a Compare-Match condition occurred to the Timer Compare Match Register 1 (TCMR1). When the value set in the TCMR1 matches to Cycle Time Register (TCMR1 = CYCTR), this bit is set if TTCR0 bit11 = 1. Please note that this bit is read-only and is cleared when IRR15 (Timer Compare Match Interrupt 1) is cleared.

| Bit2: TSR2 | Description                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | Timer Compare Match has not occurred to the TCMR1 (Initial value)<br>[Clearing condition] Writing '1' to IRR15 (Timer Compare Match Interrupt 1) |
| 1          | Timer Compare Match has occurred to the TCMR1<br>[Setting condition]<br>TCMR1 matches to Cycle Time (TCMR1 = CYCTR), if TTCR0 bit11 = 1.         |

**Bit 1 — Timer Compare Match Flag 0 (TSR1):** Indicates that a Compare-Match condition occurred to the Compare Match Register 0 (TCMR0). When the value set in the TCMR0 matches to the Timer value (TCMR0 = TCNTR), this bit is set if TTCR0 bit10 = 1. Please note that this bit is read-only and is cleared when IRR14 (Timer Compare Match Interrupt 0) is cleared.

| Bit1: TSR1 | Description                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | Compare Match has not occurred to the TCMR0 (Initial value)<br>[Clearing condition] Writing '1' to IRR14 (Timer Compare Match Interrupt 0) |
| 1          | Compare Match has occurred to the TCMR0<br>[Setting condition] TCMR0 matches to the Timer value (TCMR0 = TCNTR)                            |

**Bit 0 — Timer Overrun/Next\_is\_Gap Reception/Message Error (TSR0):** This flag is assigned to three different functions. It indicates that the Timer has overrun when working in event-trigger mode, time reference message with Next\_is\_Gap set has been received in time-trigger mode, and error detected on the CAN bus has occurred in test mode, respectively. Test mode has higher priority with respect to the other settings.

| Bit0: TSR0 | Description                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | Timer (TCNTR) has not overrun in event-trigger mode (Initial value)<br>Time reference message with Next_is_Gap has not been received in time-trigger mode message error has not occurred in test mode.<br>[Clearing condition] Writing ‘1’ to IRR13 |
| 1          | [Setting condition]<br>Timer (TCNTR) has overrun and changed from H'FFFF to H'0000 in event-trigger mode.time reference message with Next_is_Gap has been received in time-trigger mode message error has occurred in test mode                     |

(5) Cycle Counter Register (CCR)

This register is a 6-bit read/write register. Its purpose is to store the number of the basic cycle for Time -Triggered Transmissions. Its value is updated in different fashions depending if RCAN-TL1 is programmed to work as a potential time master or as a time slave. If RCAN-TL1 is working as (potential) time master, CCR is:

- Incremented by one every time the cycle time (CYCTR) matches to Tx-Trigger Time of Mailbox-30 or
- Overwritten with the value contained in MSG\_DATA\_0[5:0] of Mailbox 31 when a valid reference message is received.

If RCAN-TL1 is working as a time slave, CCR is only overwritten with the value of MSG\_DATA\_0[5:0] of Mailbox 31 when a valid reference message is received.

If CMAX = 3'111, CCR is always H'0000.

- CCR (Address = H'08A)

|                |    |    |    |    |    |    |   |   |   |   |          |     |     |     |     |     |
|----------------|----|----|----|----|----|----|---|---|---|---|----------|-----|-----|-----|-----|-----|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5        | 4   | 3   | 2   | 1   | 0   |
|                | -  | -  | -  | -  | -  | -  | - | - | - | - | CCR[5:0] |     |     |     |     |     |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0        | 0   | 0   | 0   | 0   | 0   |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R | R | R/W      | R/W | R/W | R/W | R/W | R/W |

**Bits 15 to 6: Reserved.** The written value should always be ‘0’ and the returned value is ‘0’.

**Bits 5 to 0 — Cycle Counter Register (CCR):** Indicates the number of the current Base Cycle of the matrix cycle for Timer Triggered transmission.

## (6) Timer Counter Register (TCNTR)

This is a 16-bit read/write register that allows the CPU to monitor and modify the value of the Free Running Timer Counter. When the Timer meets TCMR0 (Timer Compare Match Register 0) + TTCR0 [6] is set to '1', the TCNTR is cleared to H'0000 and starts running again. In Time-Trigger mode, this timer can be used as Local Time and TTCR0[6] has to be cleared to work as a free running timer.

- Notes:
1. It is possible to write into this register only when it is enabled by the bit 15 in TTCR0. If TTCR0 bit15 = 0, TCNTR is always H'0000.
  2. There could be a delay of a few clock cycles between the enabling of the timer and the moment where TCNTR starts incrementing. This is caused by the internal logic used for the pre-scaler.

- TCNTR (Address = H'08C)

|                |             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------------|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Bit:           | 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|                | TCNTR[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| Initial value: | 0           | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |
| R/W:           | R/W*        | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* |

Note: \* The register can be written only when enabled in TTCR0[15]. Write operation is not allowed in Time Trigger mode (i.e. CMAX is not 3'b111).

**Bits 15 to 0** — Indicate the value of the Free Running Timer.

## (7) Cycle Time register (CYCTR)

This register is a 16-bit read-only register. This register shows Cycle Time = Local Time (TCNTR) - Reference\_Mark (RFMK). In ET mode this register is the exact copy of TCNTR as RFMK is always fixed to zero.

- CYCTR (Address = H'090)

|                |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------------|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit:           | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                | CYCTR[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Initial value: | 0           | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           | R           | R  | R  | R  | R  | R  | R | R | R | R | R | R | R | R | R | R |

## (8) Reference Mark Register (RFMK)

This register is a 16-bit read-only register. The purpose of this register is to capture Local Time (TCNTR) at SOF of the reference message when the message is received or transmitted successfully. In ET mode this register is not used and it is always cleared to zero.

- RFMK (Address = H'094)

|                |            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------------|------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit:           | 15         | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                | RFMK[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Initial value: | 0          | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           | R          | R  | R  | R  | R  | R  | R | R | R | R | R | R | R | R | R | R |

**Bits 15 to 0 — Reference Mark Register (RFMK):** Indicates the value of TCNTR at SOF of time reference message.

## (9) Timer Compare Match Registers (TCMR0, TCMR1, TCMR2)

These three registers are 16-bit read/write registers and are capable of generating interrupt signals, clearing-setting the Timer value (only supported by TCMR0) or clear the transmission messages in the queue (only supported by TCMR2). TCMR0 is compared with TCNTR, however, TCMR1 and TCMR2 are compared with CYCTR.

The value used for the compare can be configured independently for each register. In order to set flags, TTCR0 bit 12-10 needs to be set.

In Time-Trigger mode, TTCR0 bit6 has to be cleared by software to prevent TCNTR from being cleared.

TMCRO is for Init\_Watch\_Trigger, and TCMR2 is for Watch\_Trigger.

### Interrupt:

The interrupts are flagged by the Bit11, Bit15 and 14 in the IRR accordingly when a Compare Match occurs, and setting these bits can be enabled by Bit12, Bit11, Bit10 in TTCR0. The generation of interrupt signals itself can be prevented by the Bit11, Bit15 and Bit14 in the IMR. When a Compare Match occurs and the IRR11 (or IRR15 or IRR14) is set, the Bit3 or Bit2 or Bit1 in the TSR (Timer Status Register) is also set. Clearing the IRR bit also clears the corresponding bit of TSR.

## Timer Clear-Set:

The Timer value can only be cleared when a Compare Match occurs if it is enabled by the Bit6 in the TTCR0. TCMR1 and TCMR2 do not have this function.

## Cancellation of the messages in the transmission queue:

The messages in the transmission queue can only be cleared by the TCMR2 through setting TXCR when a Compare Match occurs while RCAN-TL1 is not in the halt status. TCMR1 and TCMR0 do not have this function.

- TCMR0 (Address = H'098)

|                |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15          | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                | TCMR0[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 1           | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
| R/W:           | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

**Bits 15 to 0 — Timer Compare Match Register (TCMR0):** Indicates the value of TCNTR when compare match occurs.

- TCMR1 (Address = H'09C)

|                |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15          | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

**Bits 15 to 0 — Timer Compare Match Register (TCMR2):** Indicates the value of CYCTR when compare match occurs.

### (10) Tx-Trigger Time Selection Register (TTTSEL)

This register is a 16-bit read/write register and specifies the Tx-Trigger Time waiting for compare match with Cycle Time. Only one bit is allowed to be set. Please don't set more bits than one, or clear all bits.

This register may only be modified during configuration mode. The modification algorithm is shown in figure 19.13.

Please note that this register is only indented for test and diagnosis. When not in test mode, this register must not be written to and the returned value is not guaranteed.

- TTTSEL (Address = H'0A4)

|                |    |              |     |     |     |     |     |     |   |   |   |   |   |   |   |   |
|----------------|----|--------------|-----|-----|-----|-----|-----|-----|---|---|---|---|---|---|---|---|
| Bit:           | 15 | 14           | 13  | 12  | 11  | 10  | 9   | 8   | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                | -  | TTTSEL[14:8] |     |     |     |     |     |     | - | - | - | - | - | - | - | - |
| Initial value: | 0  | 1            | 0   | 0   | 0   | 0   | 0   | 0   | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           | R  | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R |

Note: Only one bit is allowed to be set.

**Bit 15: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 14 to 8 —** Specifies the Tx-Trigger Time waiting for compare match with CYCTR. The bit 14 to 8 corresponds to Mailbox-30 to 24, respectively.

**Bits 7 to 0: Reserved.** The written value should always be '0' and the returned value is '0'.

## 19.4 Application Note

### 19.4.1 Test Mode Settings

The RCAN-TL1 has various test modes. The register TST[2:0] (MCR[10:8]) is used to select the RCAN-TL1 test mode. The default (initialised) settings allow RCAN-TL1 to operate in Normal mode. The following table is examples for test modes.

Test Mode can be selected only while in configuration mode. The user must then exit the configuration mode (ensuring BCR0/BCR1 is set) in order to run the selected test mode.

| Bit10:<br>TST2 | Bit9:<br>TST1 | Bit8:<br>TST0 | Description                          |
|----------------|---------------|---------------|--------------------------------------|
| 0              | 0             | 0             | Normal Mode (initial value)          |
| 0              | 0             | 1             | Listen-Only Mode (Receive-Only Mode) |
| 0              | 1             | 0             | Self Test Mode 1 (External)          |
| 0              | 1             | 1             | Self Test Mode 2 (Internal)          |
| 1              | 0             | 0             | Write Error Counter                  |
| 1              | 0             | 1             | Error Passive Mode                   |
| 1              | 1             | 0             | Setting prohibited                   |
| 1              | 1             | 1             | Setting prohibited                   |

- Normal Mode:** RCAN-TL1 operates in the normal mode.
- Listen-Only Mode:** ISO-11898 requires this mode for baud rate detection. The Error Counters are cleared and disabled so that the TEC/REC does not increase the values, and the CTxn (n = 0, 1) Output is disabled so that RCAN-TL1 does not generate error frames or acknowledgment bits. IRR13 is set when a message error occurs.
- Self Test Mode 1:** RCAN-TL1 generates its own Acknowledge bit, and can store its own messages into a reception mailbox (if required). The CRxn/CTxn (n = 0, 1) pins must be connected to the CAN bus.
- Self Test Mode 2:** RCAN-TL1 generates its own Acknowledge bit, and can store its own messages into a reception mailbox (if required). The CRxn/CTxn (n = 0, 1) pins do not need to be connected to the CAN bus or any external devices, as the internal CTxn (n = 0, 1) is looped back to the internal CRxn (n = 0, 1). CTxn (n = 0, 1) pin outputs only recessive bits and CRxn (n = 0, 1) pin is disabled.
- Write Error Counter:** TEC/REC can be written in this mode. RCAN-TL1 can be forced to become an Error Passive mode by writing a value greater than 127 into the Error Counters. The value written into TEC is used to write into REC, so only the same value can be set to these registers. Similarly, RCAN-TL1 can be forced to become an Error Warning by writing a value greater than 95 into them.
- RCAN-TL1 needs to be in Halt Mode when writing into TEC/REC (MCR1 must be "1" when writing to the Error Counter). Furthermore this test mode needs to be exited prior to leaving Halt mode.
- Error Passive Mode:** RCAN-TL1 can be forced to enter Error Passive mode.  
Note: The REC will not be modified by implementing this Mode. However, once running in Error Passive Mode, the REC will increase normally should errors be received. In this Mode, RCAN-TL1 will enter BusOff if TEC reaches 256 (Dec). However when this mode is used RCAN-TL1 will not be able to become Error Active. Consequently, at the end of the Bus Off recovery sequence, RCAN-TL1 will move to Error Passive and not to Error Active.

When message error occurs, IRR13 is set in all test modes.

## 19.4.2 Configuration of RCAN-TL1

RCAN-TL1 is considered in configuration mode or after a H/W (Power On Reset)/S/W (MCR[0]) reset or when in Halt mode. In both conditions RCAN-TL1 cannot join the CAN Bus activity and configuration changes have no impact on the traffic on the CAN Bus.

- After a Reset request

The following sequence must be implemented to configure the RCAN-TL1 after (S/W or H/W) reset. After reset, all the registers are initialised, therefore, RCAN-TL1 needs to be configured before joining the CAN bus activity. Please read the notes carefully.

- Notes:
1. SW reset could be performed at any time by setting MCR[0] = 1.
  2. Mailboxes are comprised of RAMs, therefore, please initialise all the mailboxes enabled by MBC.
  3. If there is no TXPR set, RCAN-TL1 will receive the next incoming message. If there is a TXPR(s) set, RCAN-TL1 will start transmission of the message and will be arbitrated by the CAN bus. If it loses the arbitration, it will become a receiver.
  4. Timer can be started at any time after the Timer Control regs and Tx-Trigger Time are set.

**Figure 19.14 Reset Sequence**

- Halt mode

When RCAN-TL1 is in Halt mode, it cannot take part to the CAN bus activity. Consequently the user can modify all the requested registers without influencing existing traffic on the CAN Bus. It is important for this that the user waits for the RCAN-TL1 to be in halt mode before to modify the requested registers - note that the transition to Halt Mode is not always immediate (transition will occurs when the CAN Bus is idle or in intermission). After RCAN-TL1 transit to Halt Mode, GSR4 is set.

Once the configuration is completed the Halt request needs to be released. RCAN-TL1 will join CAN Bus activity after the detection of 11 recessive bits on the CAN Bus.

- Sleep mode

When RCAN-TL1 is in sleep mode the clock for the main blocks of the IP is stopped in order to reduce power consumption. Only the following user registers are clocked and can be accessed: MCR, GSR, IRR and IMR. Interrupt related to transmission (TXACK and ABACK) and reception (RXPR and RFPR) cannot be cleared when in sleep mode (as TXACK, ABACK, RXPR and RFPR are not accessible) and must to be cleared beforehand.

The following diagram shows the flow to follow to move RCAN-TL1 into sleep mode.

Figure 19.15 shows allowed state transitions.

- Please don't set MCR5 (Sleep Mode) without entering Halt Mode.
- After MCR1 is set, please don't clear it before GSR4 is set and RCAN-TL1 enters Halt Mode.

**Figure 19.15 Halt Mode/Sleep Mode**

- Notes:
1. MCR5 can be cleared by automatically by detecting a dominant bit on the CAN Bus if MCR7 is set or by writing '0'.
  2. MCR1 is cleared in SW. Clearing MCR1 and setting MCR5 have to be carried out by the same instruction.
  3. MCR1 must not be cleared in SW, before GSR4 is set. MCR1 can be set automatically in HW when RCAN-TL1 moves to Bus Off and MCR14 and MCR6 are both set.
  4. When MCR5 is cleared and MCR1 is set at the same time, RCAN-TL1 moves to Halt Request. Right after that, it moves to Halt Mode with no reception/transmission.

The following table shows conditions to access registers.

## RCAN-TL1 Registers

| Status                                    | Mode | MBIMR      |            |                  |                      |                   |                                    |                   |                                    | Mailbox<br>Trigger<br>Time TT<br>control |
|-------------------------------------------|------|------------|------------|------------------|----------------------|-------------------|------------------------------------|-------------------|------------------------------------|------------------------------------------|
|                                           |      | MCR<br>GSR | IRR<br>IMR | BCR              | timer<br>TT_register | Flag_<br>register | Mailbox<br>(ctrl0, LAFM)           | Mailbox<br>(data) | Mailbox<br>(ctrl1)                 |                                          |
| Reset                                     |      | yes        | yes        | yes              | yes                  | yes               | yes                                | yes               | yes                                | yes                                      |
| Transmission<br>Reception<br>Halt Request |      | yes        | yes        | no* <sup>1</sup> | yes                  | yes               | no* <sup>1</sup> yes* <sup>2</sup> | yes* <sup>2</sup> | no* <sup>1</sup> yes* <sup>2</sup> | yes* <sup>2</sup>                        |
| Halt                                      |      | yes        | yes        | no* <sup>1</sup> | yes                  | yes               | yes                                | yes               | yes                                | yes                                      |
| Sleep                                     |      | yes        | yes        | no               | no                   | no                | no                                 | no                | no                                 | no                                       |

Notes: 1. No hardware protection.

2. When TXPR is not set.

### 19.4.3 Message Transmission Sequence

- Message Transmission Request

The following sequence is an example to transmit a CAN frame onto the bus. As described in the previous register section, please note that IRR8 is set when one of the TXACK or ABACK bits is set, meaning one of the Mailboxes has completed its transmission or transmission abortion and is now ready to be updated for the next transmission, whereas, the GSR2 means that there is currently no transmission request made (No TXPR flags set).

**Figure 19.16 Transmission request**

- Internal Arbitration for transmission

The following diagram explains how RCAN-TL1 manages to schedule transmission-requested messages in the correct order based on the CAN identifier. 'Internal arbitration' picks up the highest priority message amongst transmit-requested messages.

**Figure 19.17 Internal Arbitration for transmission**

The RCAN-TL1 has two state machines. One is for transmission, and the other is for reception.

- 1-1: When a TXPR bit(s) is set while the CAN bus is idle, the internal arbitration starts running immediately and the transmission is started.
- 1-2: Operations for both transmission and reception starts at SOF. Since there is no reception frame, RCAN-TL1 becomes transmitter.
- 2-1: At crc delimiter, internal arbitration to search next message transmitted starts.
- 2-2: Operations for both transmission and reception starts at SOF. Because of a reception frame with higher priority, RCAN-TL1 becomes receiver. Therefore, Reception is carried out instead of transmitting Frame-3.
- 3-1: At crc delimiter, internal arbitration to search next message transmitted starts.
- 3-2: Operations for both transmission and reception starts at SOF. Since a transmission frame has higher priority than reception one, RCAN-TL1 becomes transmitter.

Internal arbitration for the next transmission is also performed at the beginning of each error delimiter in case of an error is detected on the CAN Bus. It is also performed at the beginning of error delimiters following overload frame.

As the arbitration for transmission is performed at CRC delimiter, in case a remote frame request is received into a Mailbox with ATX = 1 the answer can join the arbitration for transmission only at the following Bus Idle, CRC delimiter or Error Delimiter.

Depending on the status of the CAN bus, following the assertion of the TXCR, the corresponding Message abortion can be handled with a delay of maximum 1 CAN Frame.

## (1) Time Triggered Transmission

RCAN-TL1 offers a H/W support to perform communication in Time Trigger mode in line with the emerging ISO-11898-4 Level 1 Specification.

This section reports the basic procedures to use this mode.

- Setting Time Trigger Mode

In order to set up the time trigger mode the following settings need to be used.

- CMAX in CMAX\_TEW must be programmed to a value different from 3'b111.
- Bit 15 in TTCR0 has to be set, to start TCNTR.
- Bit 6 in TTCR0 has to be cleared to prevent TCNTR from being cleared after a match.
- DART in Mailboxes used for time-triggered transmission cannot be used, since for Time Triggered Mailboxes, TXPR is not cleared to support periodic transmission.

- Roles of Registers

The user registers of RCAN-TL1 can be used to handle the main functions requested by the TTCAN standard.

|                  |                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------|
| TCNTR            | Local Time                                                                                                                      |
| RFMK             | Ref_Mark                                                                                                                        |
| CYCTR            | Cycle Time = TCNTR - RFMK                                                                                                       |
| RFTROFF          | Ref_Trigger_Offset for Mailbox-30                                                                                               |
| Mailbox-31       | Mailbox dedicated to the reception of time reference message                                                                    |
| Mailbox-30       | Mailbox dedicated to the transmission of time reference message when working as a potential time master                         |
| Mailbox-29 to 24 | Mailboxes supporting time-triggered transmission                                                                                |
| Mailbox-23 to 16 | Mailboxes supporting reception without timestamp (may also be implemented as Mailboxes supporting Event Triggered transmission) |
| Mailbox-15 to 0  | Mailboxes supporting reception with timestamp (may also be implemented as Mailboxes supporting Event Triggered transmission)    |
| Tx-Trigger Time  | Time_Mark to specify when a message should be transmitted                                                                       |

|        |                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------|
| CMAX   | Specifies the maximum number of basic cycles when working as potential time master                       |
| TEW    | Specify the width of Tx_Enable                                                                           |
| TCMR0  | Init_Watch_Trigger (compare match with Local Time)                                                       |
| TCMR1  | Compare match with Cycle Time to monitor users-specified events                                          |
| TCMR2  | Watch_Trigger (compare match with Cycle Time). This can be programmed to abort all pending transmissions |
| TTW    | Specifies the attribute of a time window used for transmission                                           |
| TTTSEL | Specifies the next Mailbox waiting for transmission                                                      |

- Time Master/Time Slave

RCAN-TL1 can be programmed to work as a potential time master of the network or as a time slave. The following table shows the settings and the operation automatically performed by RCAN-TL1 in each mode.

| mode                       | requested setting                                                                                            | function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|--------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- Setting Tx-Trigger Time

The Tx-Trigger Time(TTT) must be set in ascending order shown below, and the difference between them has to satisfy the following expressions. TEW in the following expressions is the register value.

$$\text{TTT (Mailbox-24)} < \text{TTT (Mailbox-25)} < \text{TTT (Mailbox-26)} < \text{TTT (Mailbox-27)} < \text{TTT (Mailbox-28)} < \text{TTT (Mailbox-29)} < \text{TTT (Mailbox-30)}$$

and

$$\text{TTT (Mailbox-i)} - \text{TTT (Mailbox- i-1)} > \text{TEW} + \text{the maximum frame length} + 9$$

TTT (Mailbox-24) to TTT (Mailbox-29) correspond to Time\_Marks, and TTT (Mailbox-30) corresponds to Time\_Ref showing the length of a basic cycle, respectively when working as potential time master.

The above limitation is not applied to mailboxes which are not set as time-triggered transmission.

**Important:** Because of limitation on setting Tx-Trigger Time, only one Mailbox can be assigned to one time window.

Figure 19.18 Limitation on Tx-Trigger Time

The value of TCMR2 as Watch\_Trigger has to be larger than TTT(Mailbox-30), which shows the length of a basic cycle.

Figures 19.19 and 19.20 show examples of configurations for (Potential) Time Master and Time Slave. “L” in diagrams shows the length in time of the time reference messages.

Figure 19.19 (Potential) Time Master

**Figure 19.20 Time Slave**

- Function to be implemented by software

Some of the TTCAN functions need to be implemented in software. The main details are reported hereafter. Please refer to ISO-11898-4 for more details.

#### — Change from Init\_Watch\_Trigger to Watch\_Trigger

RCAN-TL1 offers the two registers TCMR0 and TCMR2 as H/W support for Init\_Watch\_Trigger and Watch\_Trigger respectively. The SW is requested to enable TCMR0 and disable TCMR2 up to the first reference message is detected on the CAN Bus and then disable TCMR0 and enable TCMR2.- Schedule Synchronization state machine.

Only reception of Next\_is\_Gap interrupt is supported. The application needs to take care of stopping all transmission at the end of the current basic cycle by setting the related TXCR flags.Master-Slave Mode control.

Only automatic cycle time synchronization and CCR increment is supported.

#### — Message status count

Software has to count scheduling errors for periodic messages in exclusive windows.

- Message Transmission Request for Time Triggered communication

When the Time Triggered mode is used communications must fulfil the ISO11898-4 requirements.

The following procedure should be used.

- Send RCAN-TL1 to reset or halt mode
- Set TCMR0 to the Init\_Watch\_Trigger (0xFFFF)
- Enable TCMR0 compare match setting bit 10 of TTCR0
- Set TCMR2 to the specified Watch\_Trigger value
- Keep TCMR2 compare match disabled by keeping cleared the bit 12 of TTCR0
- Set CMAX to the requested value (different from 111 bin)
- Set TEW to the requested value
- Configure the necessary Mailboxes for Time Trigger transmission and reception
- Set LAFM for the 3 LSBs of Mailbox 31
- Configure MCR, BCR1 and BCR0 to the requested values
- If working as a potential time master:
  - Set RFTROFF to the requested Init\_Ref\_Offset value
  - Set TXPR for Mailbox 30
  - Write H'4000 into TTTSEL
- Enable the TCNTR timer through the bit 15 of TTCR0
- Move to Transmission\_Reception mode
- Wait for the reception or transmission of a valid reference message or for TCMR0 match
- If the local time reaches the value of TCMR0 the Init\_Watch\_Trigger is reached and the application needs to set TXCR for Mailbox 30 and start again
- If the reference message is transmitted (TXACK[30] is set) set RFTROFF to zero
- If a valid reference message is received (RXPR[31] is set) then:
  - If 3 LSBs of ID of Mailbox 31 have high priority than the 3 LSBs of Mailbox 30 (if working as potential time master) keep RFTROFF to Init\_Ref\_Offset
  - If 3 LSBs of ID of Mailbox 31 have lower priority than the 3 LSBs of Mailbox 30 (if working as potential time master) decrement by 1 the value in RFTROFF
- Disable TCMR0 compare match by clearing bit 10 of TTCR0
- Enable TCMR2 compare match by setting bit 12 of TTCR0
- Only after two reference messages have been detected on the CAN Bus (transmitted or received) can the application set TXPR for the other Time Triggered Mailboxes.

If, at any time, a reference message cannot be detected on the CAN Bus, and the cycle time CYCTR reaches TCMR2, RCAN-TL1 automatically aborts all pending transmissions (including the Reference Message).

The following is the sequence to request further transmission in Time Triggered mode.

**Figure 19.21 Message transmission request**

S/W has to ensure that a message is updated before a Tx trigger for transmission occurs.

When the CYCTR reaches to TTT (Tx-Trigger Time) of a Mailbox and CCR matches with the programmed cycle for transmission, RCAN-TL1 immediately transfers the message into the Tx buffer. At this point, RCAN-TL1 will attempt a transmission within the specified Time Enable Window. If RCAN-TL1 misses this time slot, it will suspend the transmission request up to the next Tx Trigger, keeping the corresponding TXPR bit set to '1' if the transmission is periodic (Mailbox-24 to 30). There are three factors that may cause RCAN-TL1 to miss the time slot –

1. The CAN bus currently used
2. An error on the CAN bus during the time triggered message transmission
3. Arbitration loss during the time triggered message transmission

In case of Merged Arbitrating Window the slot for transmission goes from the Tx\_Trig of the Mailbox opening the Window (TTW = 10 bin) to the end to the TEW of the Mailbox closing the Window (TTW = 11 bin). The TXPR can be modified at any time. RCAN-TL1 ensures the transmission of Time Triggered messages is always scheduled correctly. However, in order to guarantee the correct schedule, there are some important rules that are :

- TTT (Tx Trigger Time) can be modified during configuration mode.
- TTT cannot be set outside the range of Time\_Ref, which specifies the length of basic cycle. This could cause a scheduling problem.
- TXPR is not automatically cleared for periodic transmission. If a periodic transmission needs to be cancelled, the corresponding TXCR bit needs to be set by the application.

- Example of Time Triggered System

The following diagram shows a simple example of how time trigger system works using RCAN-TL1 in time slave mode.

**Figure 19.22 Example of Time trigger system as Time Slave**

The following settings were used in the above example:

|            | <b>rep_factor<br/>(register)</b> | <b>Offset</b> | <b>TTW[1:0]</b> | <b>MBC[2:0]</b> |
|------------|----------------------------------|---------------|-----------------|-----------------|
| Mailbox-24 | 3'b001                           | 6'b000000     | 2'b00           | 3'b000          |
| Mailbox-25 | 3'b000                           | 6'b000000     | 2'b10           | 3'b000          |
| Mailbox-26 | 3'b000                           | 6'b000000     | 2'b10           | 3'b000          |
| Mailbox-27 | 3'b000                           | 6'b000000     | 2'b11           | 3'b000          |
| Mailbox-28 | 3'b010                           | 6'b000001     | 2'b00           | 3'b000          |
| Mailbox-29 | 3'b011                           | 6'b000110     | 2'b01           | 3'b000          |
| Mailbox-30 | —                                | —             | —               | 3'b111          |
| Mailbox-31 | —                                | —             | —               | 3'b011          |

CMAx = 3'b011, TXPR[30] = 0

During merged arbitrating window, request by time-triggered transmission is served in the way of FCFS (First Come First Served). For example, if Mailbox-25 cannot be transmitted between Tx-Trigger Time 25 (TTT25) and TTT26, Mailbox-25 has higher priority than Mailbox-26 between TTT26 and 28.

MBC needs to be set into 3'b111, in order to disable time-triggered transmission. If RCAN-TL1 is Time Master, MBC[30] has to be 3'b000 and time reference window is automatically recognized as arbitrating window.

- Timer Operation

Figure 19.23 shows the timing diagram of the timer. By setting Tx-Trigger Time = n, time trigger transmission starts between CYCTR = n + 2 and CYCTR = n + 3.

(1) Clear TCNTR by TCMR0 in Event-Trigger mode

(2) Interrupt generation by TCMR0/1/2 in Event-Trigger mode

(3) Interrupt generation by TCMR0 in Time-Trigger mode

(4) Interrupt generation by TCMR1/2 in Time-Trigger mode

(5) Time-triggered transmission request in Time-Trigger mode, during bus idle

**Figure 19.23 Timing Diagram of Timer**

During merged arbitrating window, event-trigger transmission is served after completion of time-triggered transmission. For example, If transmission of Mailbox-25 is completed and CYCTR doesn't reach TTT26, event-trigger transmission starts based on message transmission priority specified by MCR2. TXPR of time-triggered transmission is not cleared after transmission completion, however, that of event-triggered transmission is cleared.

Note: that in the case that the TXPR is not set for the Mailbox which is assigned to close the Merged Arbitrating Window (MAW), then the MAW will still be closed (at the end of the TEW following the TTT of the assigned Mailbox.

Please refer to Table Roles of Mailboxes in section 19.3.2, Mailbox Structure.

### 19.4.4 Message Receive Sequence

The diagram below shows the message receive sequence.

**Figure 19.24 Message receive sequence**

When RCAN-TL1 recognises the end of the Arbitration field while receiving a message, it starts comparing the received identifier to the identifiers set in the Mailboxes, starting from Mailbox-31 down to Mailbox-0. It first checks the MBC if it is configured as a receive box, and reads LAFM, and reads the CAN-ID of Mailbox-31 (if configured as receive) to finally compare them to the received ID. If it does not match, the same check takes place at Mailbox-30 (if configured as receive). Once RCAN-TL1 finds a matching identifier, it stores the number of Mailbox-[N] into an internal buffer, stops the search, and goes back to idle state, waiting for the EndOfFrame (EOF) to come. When the 6<sup>th</sup> bit of EOF is notified by the CAN Interface logic, the received message is written or abandoned, depending on the NMC bit. No modification of configuration during communication is allowed. Entering Halt Mode is one of ways to modify configuration. If it is written into the corresponding Mailbox, including the CAN-ID, i.e., there is a possibility that the CAN-ID is overwritten by a different CAN-ID of the received message due to the LAFM used. This also implies that, if the identifier of a received message matches to ID + LAFM of 2 or more Mailboxes, the higher numbered Mailbox will always store the relevant messages and the lower numbered Mailbox will never receive messages. Therefore, the settings of the identifiers and LAFMs need to be carefully selected.

With regards to the reception of data and remote frames described in the above flow diagram the clearing of the UMSR flag after the reading of IRR is to detect situations where a message is overwritten by a new incoming message stored in the same mailbox (if its NMC = 1) while the interrupt service routine is running. If during the final check of UMSR a overwrite condition is detected the message needs to be discarded and read again.

In case UMSR is set and the Mailbox is configured for overrun (NMC = 0) the message is still valid, however it is obsolete as it is not reflecting the latest message monitored on the CAN Bus.

Please access the full Mailbox content before clearing the related RXPR/RFPR flag.

Please note that in the case a received remote frame is overwritten by a data frame, both the remote frame receive interrupt (IRR2) and data frame received interrupt (IRR1) and also the Receive Flags (RXPR and RFPR) are set. In an analogous way, the overwriting of a data frame by a remote frame, leads to setting both IRR2 and IRR1.

When a message is received and stored into a Mailbox all the fields of the data not received are stored as zero. The same applies when a standard frame is received. The extended identifier part (EXTID[17:0]) is written as zero.

### 19.4.5 Reconfiguration of Mailbox

When re-configuration of Mailboxes is required, the following procedures should be taken.

- Change configuration of transmit box

Two cases are possible.

- Change of ID, RTR, IDE, LAFM, Data, DLC, NMC, ATX, DART

This change is possible only when MBC = 3'b000. Confirm that the corresponding TXPR is not set. The configuration (except MBC bit) can be changed at any time.

- Change from transmit to receive configuration (MBC)

Confirm that the corresponding TXPR is not set. The configuration can be changed only in Halt or reset state. Please note that it might take longer for RCAN-TL1 to transit to halt state if it is receiving or transmitting a message (as the transition to the halt state is delayed until the end of the reception/transmission), and also RCAN-TL1 will not be able to receive/transmit messages during the Halt state.

In case RCAN-TL1 is in the Bus Off state the transition to halt state depends on the configuration of the bit 6 of MCR and also bit and 14 of MCR.

- Change configuration (ID, RTR, IDE, LAFM, Data, DLC, NMC, ATX, DART, MBC) of receiver box or Change receiver box to transmitter box

The configuration can be changed only in Halt Mode.

RCAN-TL1 will not lose a message if the message is currently on the CAN bus and RCAN-TL1 is a receiver. RCAN-TL1 will be moving into Halt Mode after completing the current reception. Please note that it might take longer if RCAN-TL1 is receiving or transmitting a message (as the transition to the halt state is delayed until the end of the reception/transmission), and also RCAN-TL1 will not be able to receive/transmit messages during the Halt Mode.

In case RCAN-TL1 is in the Bus Off state the transition to halt mode depends on the configuration of the bit 6 and 14 of MCR.

**Figure 19.25 Change ID of receive box or Change receive box to transmit box**

## 19.5 Interrupt Sources

Table 19.2 lists the RCAN-TL1 interrupt sources. These sources can be masked. Masking is implemented using the mailbox interrupt mask registers (MBIMR) and interrupt mask register (IMR). For details on the interrupt vector of each interrupt source, see section 6, Interrupt Controller (INTC).

**Table 19.2 RCAN-TL1-n\*<sup>1</sup> Interrupt Sources**

| Interrupt                                      | Description                                             | Interrupt Flag     | DMAC Activation        |
|------------------------------------------------|---------------------------------------------------------|--------------------|------------------------|
| ERSn* <sup>1</sup>                             | Error Passive Mode (TEC $\geq$ 128 or REC $\geq$ 128)   | IRR5               | Not possible           |
|                                                | Bus Off (TEC $\geq$ 256)/Bus Off recovery               | IRR6               |                        |
|                                                | Error warning (TEC $\geq$ 96)                           | IRR3               |                        |
|                                                | Error warning (REC $\geq$ 96)                           | IRR4               |                        |
| OVRn* <sup>1</sup>                             | Reset/halt/CAN sleep transition                         | IRR0               |                        |
|                                                | Overload frame transmission                             | IRR7               |                        |
|                                                | Unread message overwrite (overrun)                      | IRR9               |                        |
|                                                | Start of new system matrix                              | IRR10              |                        |
|                                                | TCMR2 compare match                                     | IRR11              |                        |
|                                                | Bus activity while in sleep mode                        | IRR12              |                        |
|                                                | Timer overrun/Next_is_Gap reception/message error       | IRR13              |                        |
|                                                | TCMR0 compare match                                     | IRR14              |                        |
| RM0n* <sup>1*2</sup> ,<br>RM1n* <sup>1*2</sup> | Data frame reception                                    | IRR1* <sup>3</sup> | Possible* <sup>4</sup> |
|                                                | Remote frame reception                                  | IRR2* <sup>3</sup> |                        |
| SLEn* <sup>1</sup>                             | Message transmission/transmission disabled (slot empty) | IRR8               | Not possible           |

Notes: 1. n = 0, 1

2. RM0 is an interrupt generated by the remote request pending flag for mailbox 0 (RFPR0[0]) or the data frame receive flag for mailbox 0 (RXPR0[0]). RM1 is an interrupt generated by the remote request pending flag for mailbox n (RFPR0[n]) or the data frame receive flag for mailbox n (RXPR0[n]) (n = 1 to 31).
3. IRR1 is a data frame received interrupt flag for mailboxes 0 to 31, and IRR2 is a remote frame request interrupt flag for mailboxes 0 to 31.
4. The DMAC is activated only by an RM0n interrupt.

## 19.6 DMAC Interface

The DMAC can be activated by the reception of a message in RCAN-TL1 mailbox 0. When DMAC transfer ends after DMAC activation has been set, flags of RXPR0 and RFPR0 are cleared automatically. An interrupt request due to a receive interrupt from the RCAN-TL1 cannot be sent to the CPU in this case. Figure 19.26 shows a DMAC transfer flowchart.

**Figure 19.26 DMAC Transfer Flowchart**

## 19.7 CAN Bus Interface

A bus transceiver IC is necessary to connect this LSI to a CAN bus. A Renesas HA13721 transceiver IC and its compatible products are recommended. As the CRx and CTx pins use 3 V, an external level shifter is necessary. Figure 19.27 shows a sample connection diagram.

**Figure 19.27 High-Speed Interface Using HA13721**

## 19.8 Setting I/O Ports for RCAN-TL1

The I/O ports for the RCAN-TL1 must be specified before or during the configuration mode. For details on the settings of I/O ports, see section 25, Pin Function Controller (PFC). Two methods are available using three channels of the RCAN-TL1 in this LSI.

- Using RCAN-TL1 as a 2-channel module (channels 0 and 1)  
Each channel has 32 Mailboxes.
- Using RCAN-TL1 as a 1-channel module (channels 0 and 1 functioning as a single channel)

When the second method is used, see section 19.9.1, Notes on Port Setting for Multiple Channels Used as Single Channel.

Figures 19.28 and 19.29 show connection examples for individual port settings.

**Figure 19.28 Connection Example when Using RCAN-TL1 as 2-Channel Module  
(32 Mailboxes × 2 Channels)**

**Figure 19.29 Connection Example when Using RCAN-TL1 as 1-Channel Module  
(64 Mailboxes × 1 Channel)**

## 19.9 Usage Notes

### 19.9.1 Notes on Port Setting for Multiple Channels Used as Single Channel

The RCAN-TL1 in this LSI has two channels and some of these channels can be used as a single channel. When using multiple channels as a single channel, keep the following in mind.

**Figure 19.30 Connection Example when Using RCAN-TL1 as 1-Channel Module (64 Mailboxes × 1 Channel)**

1. No ACK error is detected even when any other nodes are not connected to the CAN bus. This occurs when channel 1 transmits an ACK in the ACK field in response to a message channel 0 has transmitted.

Channel 1 receives a message which channel 0 has transmitted on the CAN bus and then transmits an ACK in the ACK field. After that, channel 0 receives the ACK.

To avoid this, make channel 1 which is not currently used for transmission the listen-only mode (TST[2:0] = B'001) or the reset state (MCR0 = 1). With this setting, only a channel which transmits a message transmits an ACK.

2. Internal arbitration for channels 0 and 1 is independently controlled to determine the order of transmission.

Although the internal arbitration is performed on 31 Mailboxes at a time, it is not performed on 64 Mailboxes at a time even though multiple channels function as a single channel.

3. Do not set the same transmission message ID in both channels 0 and 1.

Two messages may be transmitted from the two channels after arbitration on the CAN bus.

## Section 20 A/D Converter (ADC)

This LSI includes a 10-bit successive-approximation A/D converter allowing selection of up to eight analog input channels.

### 20.1 Features

- Resolution: 10 bits
- Input channels: 8
- Minimum conversion time: 3.9  $\mu$ s per channel
- Absolute accuracy:  $\pm 4$  LSB
- Operating modes: 3
  - Single mode: A/D conversion on one channel
  - Multi mode: A/D conversion on one to four channels or on one to eight channels
  - Scan mode: Continuous A/D conversion on one to four channels or on one to eight channels
- Data registers: 8

Conversion results are held in a 16-bit data register for each channel
- Sample-and-hold function
- A/D conversion start methods: 3
  - Software
  - Conversion start trigger from multi-function timer pulse unit 2 (MTU2)
  - External trigger signal
- Interrupt source

An A/D conversion end interrupt (ADI) request can be generated on completion of A/D conversion.
- Module standby mode can be set

Figure 20.1 shows a block diagram of the A/D converter.

**Figure 20.1 Block Diagram of A/D Converter**

## 20.2 Input/Output Pins

Table 20.1 summarizes the A/D converter's input pins.

**Table 20.1 Pin Configuration**

| Pin Name                       | Symbol                    | I/O   | Function                                              |
|--------------------------------|---------------------------|-------|-------------------------------------------------------|
| Analog power supply pin        | AVcc                      | Input | Analog power supply pin                               |
| Analog ground pin              | AVss                      | Input | Analog ground pin and A/D conversion reference ground |
| Analog reference voltage pin   | AVref                     | Input | A/D converter reference voltage pin                   |
| Analog input pin 0             | AN0                       | Input | Analog input                                          |
| Analog input pin 1             | AN1                       | Input |                                                       |
| Analog input pin 2             | AN2                       | Input |                                                       |
| Analog input pin 3             | AN3                       | Input |                                                       |
| Analog input pin 4             | AN4                       | Input |                                                       |
| Analog input pin 5             | AN5                       | Input |                                                       |
| Analog input pin 6             | AN6                       | Input |                                                       |
| Analog input pin 7             | AN7                       | Input |                                                       |
| A/D external trigger input pin | $\overline{\text{ADTRG}}$ | Input | External trigger input to start A/D conversion        |

## 20.3 Register Descriptions

The A/D converter has the following registers.

**Table 20.2 Register Configuration**

| Register Name               | Abbreviation | R/W | Initial Value | Address    | Access Size |
|-----------------------------|--------------|-----|---------------|------------|-------------|
| A/D data register A         | ADDRA        | R   | H'0000        | H'FFFE5800 | 16          |
| A/D data register B         | ADDRB        | R   | H'0000        | H'FFFE5802 | 16          |
| A/D data register C         | ADDRC        | R   | H'0000        | H'FFFE5804 | 16          |
| A/D data register D         | ADDRD        | R   | H'0000        | H'FFFE5806 | 16          |
| A/D data register E         | ADDRE        | R   | H'0000        | H'FFFE5808 | 16          |
| A/D data register F         | ADDRF        | R   | H'0000        | H'FFFE580A | 16          |
| A/D data register G         | ADDRG        | R   | H'0000        | H'FFFE580C | 16          |
| A/D data register H         | ADDRH        | R   | H'0000        | H'FFFE580E | 16          |
| A/D control/status register | ADCSR        | R/W | H'0040        | H'FFFE5820 | 16          |

20.3.1 A/D Data Registers A to H (ADDRA to ADDRH)

The sixteen A/D data registers, ADDRA to ADDRH, are 16-bit read-only registers that store the results of A/D conversion.

An A/D conversion produces 10-bit data, which is transferred for storage into the ADDR corresponding to the selected channel. The 10 bits of the result are stored in the upper bits (bits 15 to 6) of ADDR. Bits 5 to 0 of ADDR are reserved bits that are always read as 0.

Access to ADDR in 8-bit units is prohibited. ADDR must always be accessed in 16-bit units.

Table 20.3 indicates the pairings of analog input channels and ADDR.

|                |  |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------------|--|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit:           |  | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                |  |    |    |    |    |    |    |   |   |   |   | - | - | - | - | - | - |
| Initial value: |  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           |  | R  | R  | R  | R  | R  | R  | R | R | R | R | R | R | R | R | R | R |

| Bit     | Bit Name | Initial Value | R/W | Description                                                          |
|---------|----------|---------------|-----|----------------------------------------------------------------------|
| 15 to 6 |          | All 0         | R   | Bit data (10 bits)                                                   |
| 5 to 0  | —        | All 0         | R   | Reserved                                                             |
|         |          |               |     | These bits are always read as 0. The write value should always be 0. |

Table 20.3 Analog Input Channels and ADDR

| Analog Input Channel | A/D Data Register where Conversion Result is Stored |
|----------------------|-----------------------------------------------------|
| AN0                  | ADDRA                                               |
| AN1                  | ADDRB                                               |
| AN2                  | ADDRC                                               |
| AN3                  | ADDRD                                               |
| AN4                  | ADDRE                                               |
| AN5                  | ADDRF                                               |
| AN6                  | ADDRG                                               |
| AN7                  | ADDRH                                               |

### 20.3.2 A/D Control/Status Register (ADCSR)

ADCSR is a 16-bit readable/writable register that selects the mode, controls the A/D converter, and enables or disables starting of A/D conversion by external trigger input.

|                |                     |      |      |    |           |     |     |          |     |          |     |     |         |     |     |     |
|----------------|---------------------|------|------|----|-----------|-----|-----|----------|-----|----------|-----|-----|---------|-----|-----|-----|
| Bit:           | 15                  | 14   | 13   | 12 | 11        | 10  | 9   | 8        | 7   | 6        | 5   | 4   | 3       | 2   | 1   | 0   |

## [Legend]

x: Don't care

- Notes:
- The flag can only be cleared by writing 0 to it after reading it as 1. However, in the following cases as well the flag is cleared by writing 0 to it:
    - (1) When the CPU reads the value of ADF as 1
    - (2) When ADF is cleared to 0 by the DMAC reading ADDR
    - (3) When the ADF flag is set to 1 at A/D conversion end
    - (4) When the CPU writes 0 to ADF
  - Set the A/D conversion time to minimum or more values to meet the absolute accuracy of the A/D conversion characteristics.
  - $t_{\text{pcc}}$  indicates the peripheral clock (P $\phi$ ) cycle.

## 20.4 Operation

The A/D converter uses the successive-approximation method, and the resolution is 10 bits. It has three operating modes: single mode, multi mode, and scan mode. Switching the operating mode or analog input channels must be done while the ADST bit in ADCSR is 0 to prevent incorrect operation. The ADST bit can be set at the same time as the operating mode or analog input channels are changed.

### 20.4.1 Single Mode

Single mode should be selected when only A/D conversion on one channel is required.

In single mode, A/D conversion is performed once for the specified one analog input channel, as follows:

1. A/D conversion for the selected channel starts when the ADST bit in ADCSR is set to 1 by software, MTU2, or external trigger input.
2. When A/D conversion is completed, the A/D conversion result is transferred to the A/D data register corresponding to the channel.
3. After A/D conversion has completed, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated.
4. The ADST bit that remains 1 during A/D conversion is automatically cleared to 0 when A/D conversion is completed, and the A/D converter becomes idle.

When the operating mode or analog input channel selection must be changed during A/D conversion, to prevent incorrect operation, first clear the ADST bit to 0 to halt A/D conversion. After making the necessary changes, set the ADST bit to 1 to start A/D conversion again. The ADST bit can be set at the same time as the mode or channel selection is switched.

Typical operations when a single channel (AN1) is selected in single mode are described next. Figure 20.2 shows a timing diagram for this example (the bits which are set in this example belong to ADCSR).

1. Single mode is selected, input channel AN1 is selected ( $CH[2:0] = 001$ ), the A/D interrupt is enabled ( $ADIE = 1$ ), and A/D conversion is started ( $ADST = 1$ ).
2. When A/D conversion is completed, the A/D conversion result is transferred into ADDR<sub>B</sub>. At the same time the ADF flag is set to 1, the ADST bit is cleared to 0, and the A/D converter becomes idle.
3. Since  $ADF = 1$  and  $ADIE = 1$ , an ADI interrupt is requested.
4. The A/D interrupt handling routine starts.
5. The routine reads  $ADF = 1$ , and then writes 0 to the ADF flag.
6. The routine reads and processes the A/D conversion result (ADDR<sub>B</sub>).
7. Execution of the A/D interrupts handling routine ends. Then, when the ADST bit is set to 1, A/D conversion starts and steps 2 to 7 are executed.

**Figure 20.2 Example of A/D Converter Operation  
(Single Mode, One Channel (AN1) Selected)**

### 20.4.2 Multi Mode

Multi mode should be selected when performing A/D conversion once on one or more channels.

In multi mode, A/D conversion is performed once for a maximum of eight specified analog input channels, as follows:

1. A/D conversion starts from the analog input channel with the lowest number (e.g. AN0, AN1, ..., AN3) when the ADST bit in ADCSR is set to 1 by software, MTU2, or external trigger input.
2. When A/D conversion is completed on each channel, the A/D conversion result is sequentially transferred to the A/D data register corresponding to that channel.
3. After A/D conversion on all selected channels has completed, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated.
4. The ADST bit that remains 1 during A/D conversion is automatically cleared to 0 when A/D conversion is completed, and the A/D converter becomes idle. If the ADST bit is cleared to 0 during A/D conversion, A/D conversion is halted and the A/D converter becomes idle. The ADF bit is cleared by reading ADF while ADF = 1, then writing 0 to the ADF bit.

A/D conversion is to be performed once on all the specified channels. The conversion results are transferred for storage into the A/D data registers corresponding to the channels.

When the operating mode or analog input channel selection must be changed during A/D conversion, to prevent incorrect operation, first clear the ADST bit to 0 to halt A/D conversion. After making the necessary changes, set the ADST bit to 1. A/D conversion will start again from the first channel in the group. The ADST bit can be set at the same time as the mode or channel selection is changed.

Typical operations when three channels (AN0 to AN2) are selected in multi mode are described next. Figure 20.3 shows a timing diagram for this example.

1. Multi mode is selected (MDS2 = 1, MDS1 = 0), analog input channels AN0 to AN2 are selected (CH[2:0] = 010), and A/D conversion is started (ADST = 1).
2. A/D conversion of the first channel (AN0) starts. When A/D conversion is completed, the A/D conversion result is transferred into ADDRA.
3. Next, the second channel (AN1) is selected automatically and A/D conversion starts.
4. Conversion proceeds in the same way through the third channel (AN2).
5. When conversion of all selected channels (AN0 to AN2) is completed, the ADF flag is set to 1 and the ADST bit cleared to 0.
6. If the ADIE bit is set to 1 at this time, an ADI interrupt is requested.

**Figure 20.3 Example of A/D Converter Operation  
(Multi Mode, Three Channels (AN0 to AN2) Selected)**

### 20.4.3 Scan Mode

Scan mode is useful for monitoring analog inputs in a group of one or more channels at all times. In scan mode, A/D conversion is performed sequentially for a maximum of eight specified analog input channels, as follows:

1. A/D conversion starts from the analog input channel with the lowest number (e.g. AN0, AN1, ..., AN3) when the ADST bit in ADCSR is set to 1 by software, MTU2, or external trigger input.
2. When A/D conversion is completed on each channel, the A/D conversion result is sequentially transferred to the A/D data register corresponding to that channel.
3. After A/D conversion on all selected channels has completed, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated. The A/D converter starts A/D conversion again from the channel with the lowest number.
4. The ADST bit is not cleared automatically, so steps 2. and 3. are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, A/D conversion halts and the A/D converter becomes idle.

The ADF bit is cleared by reading ADF while ADF = 1, then writing 0 to the ADF bit.

When the operating mode or analog input channel selection must be changed during A/D conversion, to prevent incorrect operation, first clear the ADST bit to 0 to halt A/D conversion. After making the necessary changes, set the ADST bit to 1. A/D conversion will start again from the first channel in the group. The ADST bit can be set at the same time as the mode or channel selection is changed.

Typical operations when three channels (AN0 to AN2) are selected in scan mode are described as follows. Figure 20.4 shows a timing diagram for this example.

1. Scan mode is selected (MDS2 = 1, MDS1 = 1), analog input channels AN0 to AN2 are selected (CH[2:0] = 010), and A/D conversion is started (ADST = 1).
2. A/D conversion of the first channel (AN0) starts. When A/D conversion is completed, the A/D conversion result is transferred into ADDRA.
3. Next, the second channel (AN1) is selected automatically and A/D conversion starts.
4. Conversion proceeds in the same way through the third channel (AN2).
5. When conversion of all the selected channels (AN0 to AN2) is completed, the ADF flag is set to 1 and conversion of the first channel (AN0) starts again. If the ADIE bit is set to 1 at this time, an ADI interrupt is requested.

6. The ADST bit is not cleared automatically, so steps 2. to 4. are repeated as long as the ADST bit remains set to 1. When steps 2. to 4. are repeated, the ADF flag is kept to 1. When the ADST bit is cleared to 0, A/D conversion stops. The ADF bit is cleared by reading ADF while  $ADF = 1$ , then writing 0 to the ADF bit.

If both the ADF flag and ADIE bit are set to 1 while steps 2. to 4. are repeated, an ADI interrupt is requested at all times. To generate an interrupt on completing conversion of the third channel, clear the ADF bit to 0 after an interrupt is requested.

**Figure 20.4 Example of A/D Converter Operation**  
**(Scan Mode, Three Channels (AN0 to AN2) Selected)**

#### 20.4.4 A/D Converter Activation by External Trigger or MTU2

The A/D converter can be independently activated by an external trigger or an A/D conversion request from the MTU2. To activate the A/D converter by an external trigger or the MTU2, set the A/D trigger enable bits (TRGS[3:0]). When an external trigger or an A/D conversion request from the MTU2 is generated with this bit setting, the ADST bit is set to 1 to start A/D conversion. The channel combination is determined by bits CH2 to CH0 in ADCSR. The timing from setting of the ADST bit until the start of A/D conversion is the same as when 1 is written to the ADST bit by software.

#### 20.4.5 Input Sampling and A/D Conversion Time

The A/D converter has a built-in sample-and-hold circuit. The A/D converter samples the analog input at the A/D conversion start delay time ( $t_d$ ) after the ADST bit in ADCSR is set to 1, then starts conversion. Figure 20.5 shows the A/D conversion timing. Table 20.4 indicates the A/D conversion time.

As indicated in figure 20.5, the A/D conversion time ( $t_{\text{CONV}}$ ) includes  $t_d$  and the input sampling time ( $t_{\text{SPL}}$ ). The length of  $t_d$  varies depending on the timing of the write access to ADCSR. The total conversion time therefore varies within the ranges indicated in table 20.4.

In multi mode and scan mode, the values given in table 20.4 apply to the first conversion. In the second and subsequent conversions, time is the values given in table 20.5.

Figure 20.5 A/D Conversion Timing

| Item                            | Symbol     | CKS1 = 0 |      |      |          |      |      | CKS1 = 1 |      |      |
|---------------------------------|------------|----------|------|------|----------|------|------|----------|------|------|
|                                 |            | CKS0 = 0 |      |      | CKS0 = 1 |      |      | CKS0 = 0 |      |      |
|                                 |            | Min.     | Typ. | Max. | Min.     | Typ. | Max. | Min.     | Typ. | Max. |
| A/D conversion start delay time | $t_D$      | 11       | —    | 14   | 19       | —    | 26   | 35       | —    | 50   |
| Input sampling time             | $t_{SPL}$  | —        | 33   | —    | —        | 65   | —    | —        | 129  | —    |
| A/D conversion time             | $t_{CONV}$ | 135      | —    | 138  | 267      | —    | 274  | 531      | —    | 546  |

Note: Values in the table are the numbers of  $t_{pcyc}$ .  $t_{pcyc}$  indicates the peripheral clock (Pφ) cycle.

**Table 20.5 A/D Conversion Time (Multi Mode and Scan Mode)**

| CKS1 | CKS0 | Conversion Time (tpcyc) |
|------|------|-------------------------|
| 0    | 0    | 128 (constant)          |
|      | 1    | 256 (constant)          |
| 1    | 0    | 512 (constant)          |

Note: Values in the table are the numbers of  $t_{pcyc}$ .  $t_{pcyc}$  indicates the peripheral clock ( $P\phi$ ) cycle.

### 20.4.6 External Trigger Input Timing

A/D conversion can also be externally triggered. When the TRGS[3:0] bits in ADCSR are set to B'1001, an external trigger is input to the  $\overline{ADTRG}$  pin. The ADST bit in ADCSR is set to 1 at the falling edge of the  $\overline{ADTRG}$  pin, thus starting A/D conversion. Other operations, regardless of the operating mode, are the same as when the ADST bit has been set to 1 by software. Figure 20.6 shows the timing.

**Figure 20.6 External Trigger Input Timing**

## 20.5 Interrupt Sources and DMAC Transfer Request

The A/D converter generates an A/D conversion end interrupt (ADI) at the end of A/D conversion. An ADI interrupt request is generated if the ADIE bit is set to 1 when the ADF bit in ADCSR is set to 1 on completion of A/D conversion. Note that the direct memory access controller (DMAC) can be activated by an ADI interrupt depending on the DMAC setting. In this case, an interrupt is not issued to the CPU. If the setting to activate the DMAC has not been made, an interrupt request is sent to the CPU. Having the converted data read by the DMAC in response to an ADI interrupt enables continuous conversion to be achieved without imposing a load on software.

In single mode, set the DMAC so that DMA transfer initiated by an ADI interrupt is performed only once. In the case of A/D conversion on multiple channels in scan mode or multi mode, setting the DMA transfer count to one causes DMA transfer to finish after transferring only one channel of data. To make the DMAC transfer all conversion data, set the ADDR where A/D conversion data is stored as the transfer source address, set the number of converted channels as the transfer count, and set the TC bit in the DMA channel control register (CHCR) to 1.

When the DMAC is activated by ADI, the ADF bit in ADCSR is automatically cleared to 0 when data is transferred by the DMAC.

**Table 20.6 Relationship between Interrupt Sources and DMAC Transfer Request**

| Name | Interrupt Source   | Interrupt Flag | DMAC Activation |
|------|--------------------|----------------|-----------------|
| ADI  | A/D conversion end | ADF in ADCSR   | Possible        |

## 20.6 Definitions of A/D Conversion Accuracy

The A/D converter compares an analog value input from an analog input channel with its analog reference value and converts it to 10-bit digital data. The absolute accuracy of this A/D conversion is the deviation between the input analog value and the output digital value. It includes the following errors:

- Offset error
- Full-scale error
- Quantization error
- Nonlinearity error

These four error quantities are explained below with reference to figure 20.7. In the figure, the 10-bit A/D converter is illustrated as the 3-bit A/D converter for explanation. Offset error is the deviation between actual and ideal A/D conversion characteristics when the digital output value changes from the minimum (zero voltage) B'000000000 (000 in the figure) to B'000000001 (001 in the figure) (figure 20.7, item (1)). Full-scale error is the deviation between actual and ideal A/D conversion characteristics when the digital output value changes from B'111111110 (110 in the figure) to the maximum B'111111111 (111 in the figure) (figure 20.7, item (2)). Quantization error is the intrinsic error of the A/D converter and is expressed as 1/2 LSB (figure 20.7, item (3)). Nonlinearity error is the deviation between actual and ideal A/D conversion characteristics between zero voltage and full-scale voltage (figure 20.7, item (4)). Note that it does not include offset, full-scale, or quantization error.

**Figure 20.7 Definitions of A/D Conversion Accuracy**

## 20.7 Usage Notes

When using the A/D converter, note the following points.

### 20.7.1 Module Standby Mode Setting

Operation of the A/D converter can be disabled or enabled using the standby control register. The initial setting is for operation of the A/D converter to be halted. Register access is enabled by clearing module standby mode. For details, see section 28, Power-Down Modes.

### 20.7.2 Setting Analog Input Voltage

Permanent damage to the LSI may result if the following voltage ranges are exceeded.

1. Analog input range

During A/D conversion, voltages on the analog input pins ANn should not go beyond the following range:  $AV_{SS} \leq AN_n \leq AV_{CC}$  ( $n = 0$  to  $7$ ).

2. AVcc and AVss input voltages

Input voltages AVcc and AVss should be  $PV_{CC} - 0.3\text{ V} \leq AV_{CC} \leq PV_{CC}$  and  $AV_{SS} = PV_{SS}$ . Do not leave the AVcc and AVss pins open when the A/D converter or D/A converter is not in use and in software standby mode. When not in use, connect AVcc to the power supply (PVcc) and AVss to the ground (PVss).

3. Setting range of AVref input voltage

Set the reference voltage range of the AVref pin as  $3.0\text{ V} \leq AV_{ref} \leq AV_{CC}$ .

### 20.7.3 Notes on Board Design

In board design, digital circuitry and analog circuitry should be as mutually isolated as possible, and layout in which digital circuit signal lines and analog circuit signal lines cross or are in close proximity should be avoided as far as possible. Failure to do so may result in incorrect operation of the analog circuitry due to inductance, adversely affecting A/D conversion values.

Digital circuitry must be isolated from the analog input signals (AN0 to AN7), analog reference voltage (AVref), and analog power supply (AVcc) by the analog ground (AVss). Also, the analog ground (AVss) should be connected at one point to a stable digital ground (PVss) on the board.

### 20.7.4 Processing of Analog Input Pins

To prevent damage from voltage surges at the analog input pins (AN0 to AN7), connect an input protection circuit like the one shown in figure 20.8. The circuit shown also includes a CR filter to suppress noise. This circuit is shown as an example; the circuit constants should be selected according to actual application conditions.

Figure 20.9 shows an equivalent circuit diagram of the analog input ports and table 20.7 lists the analog input pin specifications.

**Figure 20.8 Example of Analog Input Protection Circuit**

Note: Values are reference values.

**Figure 20.9 Analog Input Pin Equivalent Circuit**

**Table 20.7 Analog Input Pin Ratings**

| Item                              | Min. | Max. | Unit |
|-----------------------------------|------|------|------|
| Analog input capacitance          | —    | 20   | pF   |
| Allowable signal-source impedance | —    | 5    | kΩ   |

### 20.7.5 Permissible Signal Source Impedance

This LSI's analog input is designed such that conversion precision is guaranteed for an input signal for which the signal source impedance is 5 kΩ or less. This specification is provided to enable the A/D converter's sample-and-hold circuit input capacitance to be charged within the sampling time; if the sensor output impedance exceeds 5 kΩ, charging may be insufficient and it may not be possible to guarantee A/D conversion precision. However, for A/D conversion in single mode with a large capacitance provided externally for A/D conversion in single mode, the input load will essentially comprise only the internal input resistance of 3 kΩ, and the signal source impedance is ignored. However, as a low-pass filter effect is obtained in this case, it may not be possible to follow an analog signal with a large differential coefficient (e.g., 5 mV/μs or greater) (see figure 20.10). When converting a high-speed analog signal, a low-impedance buffer should be inserted.

**Figure 20.10 Example of Analog Input Circuit**

### 20.7.6 Influences on Absolute Precision

Adding capacitance results in coupling with GND, and therefore noise in GND may adversely affect absolute precision. Be sure to connect AVss, etc. to an electrically stable GND.

Care is also required to insure that filter circuits mounted on the board do not pick up interference from digital signals (i.e., acting as antennas).

### 20.7.7 Note on Usage in Scan Mode and Multi Mode

Starting conversion immediately after stopping scan mode or multi mode can cause incorrect conversion results. To continue with conversion in which cases, allow a duration equivalent to the A/D conversion time for one channel to elapse after clearing ADST to 0 before starting conversion (by setting ADST to 1). (The A/D conversion time for one channel differs depending on the peripheral register settings.)

## Section 21 D/A Converter (DAC)

### 21.1 Features

- 8-bit resolution
- Two output channels
- Minimum conversion time of 10  $\mu$ s (with 20 pF load)
- Output voltage of 0 V to AVref
- D/A output hold function in software standby mode
- Module standby mode can be set

**Figure 21.1 Block Diagram of D/A Converter**

## 21.2 Input/Output Pins

Table 21.1 shows the pin configuration of the D/A converter.

**Table 21.1 Pin Configuration**

| Pin Name                     | Symbol | I/O    | Function                         |
|------------------------------|--------|--------|----------------------------------|
| Analog power supply pin      | AVcc   | Input  | Analog block power supply        |
| Analog ground pin            | AVss   | Input  | Analog block ground              |
| Analog reference voltage pin | AVref  | Input  | D/A conversion reference voltage |
| Analog output pin 0          | DA0    | Output | Channel 0 analog output          |
| Analog output pin 1          | DA1    | Output | Channel 1 analog output          |

## 21.3 Register Descriptions

The D/A converter has the following registers.

**Table 21.2 Register Configuration**

| Register Name        | Abbreviation | R/W | Initial Value | Address    | Access Size |
|----------------------|--------------|-----|---------------|------------|-------------|
| D/A data register 0  | DADR0        | R/W | H'00          | H'FFFE6800 | 8, 16       |
| D/A data register 1  | DADR1        | R/W | H'00          | H'FFFE6801 | 8, 16       |
| D/A control register | DACR         | R/W | H'1F          | H'FFFE6802 | 8, 16       |

### 21.3.1 D/A Data Registers 0 and 1 (DADR0 and DADR1)

DADR is an 8-bit readable/writable register that stores data to which D/A conversion is to be performed. Whenever analog output is enabled, the values in DADR are converted and output to the analog output pins.

DADR is initialized to H'00 by a power-on reset or in module standby mode.

### 21.3.2 D/A Control Register (DACR)

DACR is an 8-bit readable/writable register that controls the operation of the D/A converter.

DACR is initialized to H'1F by a power-on reset or in module standby mode.

|       |       | 1     |                                                                                     |

## 21.4 Operation

The D/A converter includes D/A conversion circuits for two channels, each of which can operate independently. When the DAOE bit in DACR is set to 1, D/A conversion is enabled and the conversion result is output.

An operation example of D/A conversion on channel 0 is shown below. Figure 21.2 shows the timing of this operation.

1. Write the conversion data to DADR0.
2. Set the DAOE0 bit in DACR to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time  $t_{\text{DCONV}}$  has elapsed. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is cleared to 0. The output value is expressed by the following formula:

$$\frac{\text{Contents of DADR}}{256} \times \text{AVref}$$

3. If DADR0 is written to again, the conversion is immediately started. The conversion result is output after the conversion time  $t_{\text{DCONV}}$  has elapsed.
4. If the DAOE0 bit is cleared to 0, analog output is disabled.

**Figure 21.2 Example of D/A Converter Operation**

## 21.5 Usage Notes

### 21.5.1 Module Standby Mode Setting

Operation of the D/A converter can be disabled or enabled using the standby control register. The initial setting is for operation of the D/A converter to be halted. Register access is enabled by canceling module standby mode. For details, see section 28, Power-Down Modes.

### 21.5.2 D/A Output Hold Function in Software Standby Mode

When this LSI enters software standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is equal to as during D/A conversion. If the analog power supply current needs to be reduced in software standby mode, clear the DAOE0, DAOE1, and DAE bits to 0 to disable the D/A outputs.

### 21.5.3 Setting Analog Input Voltage

The reliability of this LSI may be adversely affected if the following voltage ranges are exceeded.

1. AVcc and AVss input voltages

Input voltages AVcc and AVss should be  $PVcc - 0.3\text{ V} \leq AVcc \leq PVcc$  and  $AVss = PVss$ . Do not leave the AVcc and AVss pins open when the A/D converter or D/A converter is not in use and in software standby mode. When not in use, connect AVcc to the power supply (PVcc) and AVss to the ground (PVss).

2. Setting range of AVref input voltage

Set the reference voltage range of the AVref pin as  $3.0\text{ V} \leq AVref \leq AVcc$ .

## Section 22 AND/NAND Flash Memory Controller (FLCTL)

The AND/NAND flash memory controller (FLCTL) provides interfaces for an external AND-type flash memory and NAND-type flash memory. To take measures for errors specific to flash memory, the ECC-code generation function and error detection function are available.

Note: The flash memory using Multi Level Cell (MLC) technology is not supported by this LSI.

### 22.1 Features

#### (1) AND-Type Flash Memory Interface

- Interface directly connectable to AND-type flash memory
- Read or write in sector units (512 + 16 bytes) and ECC processing executed

An access unit of 2048 + 64 bytes, referred to as a page, is used in some datasheets for AND-type flash memory. In this manual, an access unit of 512 + 16 bytes, referred to as a sector, is always used. For products in which 2048 + 64 bytes is referred to as a page, a page is divided into units of 512 + 16 bytes (i.e. four sectors per page) for processing.

- Read or write in byte units
- Supports addresses for 2 Gbits and more by extension to 5-byte addresses

#### (2) NAND-Type Flash Memory Interface

- Interface directly connectable to NAND-type flash memory
- Read or write in sector units (512 + 16 bytes) and ECC processing executed

An access unit of 2048 + 64 bytes, referred to as a page, is used in some datasheets for NAND-type flash memory. In this manual, an access unit of 512 + 16 bytes, referred to as a sector, is always used. For products in which 2048 + 64 bytes is referred to as a page, a page is divided into units of 512 + 16 bytes (i.e. four sectors per page) for processing.

- Read or write in byte units
- Supports addresses for 2 Gbits and more by extension to 5-byte addresses

**(3) Access Modes: The FLCTL can select one of the following two access modes.**

- Command access mode: Performs an access by specifying a command to be issued from the FLCTL to flash memory, address, and data size to be input or output. Read, write, or erasure of data without ECC processing can be achieved.
- Sector access mode: Performs a read or write in sector units by specifying a sector and controls ECC-code generation and check. By specifying the number of sectors, the continuous sectors can be read or written.

**(4) Sectors and Control Codes**

- A sector is the basic unit of access and comprised of 512-byte data and 16-byte control code. The 16-byte control code includes 8-byte ECC.
- The position of the ECC in the control code can be specified in 4-byte units.
- User information can be written to the control code other than the ECC.

**(5) ECC**

- 8-byte ECC code is generated and error check is performed for a sector (512-byte data + 16-byte control code). (Note that the ECC code generation in the 16-byte control code and the number of bytes to be checked differ depending on the specifications.)
- Error correction capability is up to three errors.
- In a write operation, an ECC code is generated for data and control code prior to the ECC. The control code following the ECC is not considered.
- In a read operation, an ECC error is checked for data and control code prior to the ECC. An ECC on the control code in the FIFO is replaced with the check result by the ECC circuit, not an ECC code read from flash memory.
- An error correction is not performed even when an ECC error occurs. Error corrections must be performed by software.

**(6) Data Error**

- When a program error or erase error occurs, the error is reflected on the error source flags. Interrupts for each source can be specified.
- When a read error occurs, an ECC in the control code is other than 0. This read error is reflected on the ECC error source flag.
- When an ECC error occurs, perform an error correction, specify another sector to be replaced, and copy the contents of the block to another sector as required.

### (7) Data Transfer FIFO and Data Register

- The 224-byte data FIFO register (FLDTFIFO) is incorporated for data transfer of flash memory.
- The 32-byte control code FIFO register (FLECFIFO) is incorporated for data transfer of control code.

### (8) DMA Transfer

- By individually specifying the destinations of data and control code of flash memory to the DMA controller, data and control code can be sent to different areas.

### (9) Access Time

- The operating clock (FCLK) on the pins for the AND-/NAND-type flash memory is generated by dividing the peripheral clock ( $P\phi$ ).
- The division ratio can be specified by the FCKSEL bit and the QTSEL bit in the common control register (FLCMNCR).
- Before changing the CPG specification, the  $\overline{FLCTL}$  must be placed in a module stop state.
- In NAND-type flash memory, the FSC and  $\overline{FWE}$  pins operate with the FCLK frequency. In AND-type flash memory, the FSC pin operates with the FCLK operating frequency and the  $\overline{FWE}$  pin operates with a frequency half the FCLK operating frequency. The operating frequencies must be specified within the maximum operating frequency of memory to be connected.

Figure 22.1 shows a block diagram of the FLCTL.

**Figure 22.1 FLCTL Block Diagram**

## 22.2 Input/Output Pins

The pin configuration of the FLCTL is listed in table 22.1.

**Table 22.1 Pin Configuration**

| Pin Name                | I/O    | Corresponding Flash Memory Pin |                                | Function                                                                                                                                                                                                        |
|-------------------------|--------|--------------------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

This pin must be fixed at low in sector access mode.                                                                                                            |

Note: \* Not supported in this LSI.

## 22.3 Register Descriptions

Table 22.2 shows the FLCTL register configuration.

**Table 22.2 Register Configuration of FLCTL**

| Register Name                       | Abbreviation | R/W | Initial Value | Address     | Access Size |
|-------------------------------------|--------------|-----|---------------|-------------|-------------|
| Common control register             | FLCMNCR      | R/W | H'0000 0000   | H'FFFF F000 | 32          |
| Command control register            | FLCMDCR      | R/W | H'0000 0000   | H'FFFF F004 | 32          |
| Command code register               | FLCMCDR      | R/W | H'0000 0000   | H'FFFF F008 | 32          |
| Address register                    | FLADR        | R/W | H'0000 0000   | H'FFFF F00C | 32          |
| Address register 2                  | FLADR2       | R/W | H'0000 0000   | H'FFFF F03C | 32          |
| Data register                       | FLDATAR      | R/W | H'0000 0000   | H'FFFF F010 | 32          |
| Data counter register               | FLDTCNTR     | R/W | H'0000 0000   | H'FFFF F014 | 32          |
| Interrupt DMA control register      | FLINTDMACR   | R/W | H'0000 0000   | H'FFFF F018 | 32          |
| Ready busy timeout setting register | FLBSYTMR     | R/W | H'0000 0000   | H'FFFF F01C | 32          |
| Ready busy timeout counter          | FLBSYCNT     | R   | H'0000 0000   | H'FFFF F020 | 32          |
| Data FIFO register                  | FLDTFIFO     | R/W | H'xxxx xxxx   | H'FFFF F050 | 32          |
| Control code FIFO register          | FLECFIFO     | R/W | H'xxxx xxxx   | H'FFFF F060 | 32          |
| Transfer control register           | FLTRCR       | R/W | H'00          | H'FFFF F02C | 8           |

### 22.3.1 Common Control Register (FLCMNCR)

FLCMNCR is a 32-bit readable/writable register that specifies the type (AND/NAND) of flash memory and access mode.

### 22.3.2 Command Control Register (FLCMDRCR)

FLCMDRCR is a 32-bit readable/writable register that issues a command in command access mode, specifies address issue, and specifies source or destination of data transfer. In sector access mode, FLCMDRCR specifies the number of sector transfers.

### 22.3.4 Address Register (FLADR)

FLADR is a 32-bit readable/writable register that specifies an address to be output. The address of the size specified by the command control register is output sequentially from ADR1 in byte units. With the sector access address specification bit (ADRM<sub>D</sub>) in the command control register, it is possible to specify whether the sector number set in the address data bits is converted into an address to be output to the flash memory.

- ADR<sub>M</sub><sub>D</sub> = 1

### 22.3.7 Data Register (FLDATAR)

FLDATAR is a 32-bit readable/writable register. It stores input/output data used when 0 is written to the CDSRC bit in FLCMDCR in command access mode. FLDATAR cannot be used for reading or writing of five or more bytes of contiguous data.

## 22.3.8 Interrupt DMA Control Register (FLINTDMACR)

FLINTDMACR is a 32-bit readable/writable register that enables or disables DMA transfer requests or interrupts. A transfer request from the FLCTL to the DMAC is issued after each access mode has been started.

Bits 9 to 5 are the flag bits that indicate various errors occurred in flash memory access and whether there is a transfer request from the FIFO. Only 0 can be written to these bits. To clear a flag, write 0 to the target flag bit and 1 to the other flag bits.

Note: \* Only 0 can be written to these bits.

22.3.9    Ready Busy Timeout Setting Register (FLBSYTMR)

FLBSYTMR is a 32-bit readable/writable register that specifies the timeout time when the FRB pin is busy.

### 22.3.10 Ready Busy Timeout Counter (FLBSYCNT)

FLBSYCNT is a 32-bit read-only register.

The status of flash memory obtained by the status read is stored in the bits STAT[7:0].

The timeout time set in the bits RBTMOUT[19:0] in FLBSYTMR is copied to the bits RBTIMCNT[19:0] and counting down is started when the FRB pin is placed in a busy state. When values in the RBTIMCNT[19:0] become 0, 1 is set to the BTOERB bit in FLINTDMACR, thus notifying that a timeout error has occurred. In this case, an FLSTE interrupt request can be issued if an interrupt is enabled by the RBERINTE bit in FLINTDMACR.

| 19 to 0  | RBTIMCNT[19:0] | All 0         | R   | Ready Busy Timeout Counter<br>When the FRB pin is placed in a busy state, the values of the bits RBTMOUT[19:0] in FLBSYTMR are copied to these bits. These bits are counted down while the FRB pin is busy. A timeout error occurs when these bits are decremented to 0. |

22.3.11  Data FIFO Register (FLDTFIFO)

FLDTFIFO is used to read or write the data FIFO area.

In DMA transfer, data in this register must be specified as the destination (source). When transferring 16-byte DMA, access FLDTFIFO from the address on the 16-byte address boundary.

Note that the direction of read or write specified by the SELRW bit in FLCMDCR must match that specified in this register. When changing the read/write direction, FLDTFIFO should be cleared by setting the AC0CLR bit in FLINTDMACR before use.

| Bit     | Bit Name   | Initial Value | R/W | Description                                                                                                                        |
|---------|------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | DTFO[31:0] | H'xxxxxxxx    | R/W | Data FIFO Area Read/Write Data<br>In write: Data is written to the data FIFO area.<br>In read: Data in the data FIFO area is read. |

### 22.3.12 Control Code FIFO Register (FLECFIFO)

FLECFIFO is used to read or write the control code FIFO area.

In DMA transfer, data in this register must be specified as the destination (source). When transferring 16-byte DMA, access FLECFIFO from the address on the 16-byte address boundary.

Note that the direction of read or write specified by the SELRW bit in FLCMDCR must match that specified in this register. When changing the read/write direction, FLECFIFO should be cleared by setting the AC1CLR bit in FLINTDMACR before use.

|                |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

### 22.3.13 Transfer Control Register (FLTRCR)

Setting the TRSTRT bit to 1 initiates access to flash memory. Access completion can be checked by the TREND bit. During the transfer (from when the TRSTRT bit is set to 1 until the TREND bit is set to 1), the processing should not be forcibly ended (by setting the TRSTRT bit to 0). When reading from flash memory, TREND is set when reading from flash memory have been finished. However, if there is any read data remaining in the FIFO, the processing should not be forcibly ended until all data has been read from the FIFO.

|                |   |   |   |   |   |   |           |            |
|----------------|---|---|---|---|---|---|-----------|------------|

## 22.4 Operation

### 22.4.1 Access Sequence

The FLCTL performs accesses in several independent stages.

For example, AND-type flash memory programming consists of the following five stages.

- First command issue stage (program setup command)
- Address issue stage (program address)
- Data stage (output)
- Second command issue stage (program start command)
- Status read stage

AND-type flash memory programming access is achieved by executing these five stages sequentially. An access to flash memory is completed at the end of the final stage (status read stage).

**Figure 22.2 Programming Operation for AND-Type Flash Memory and Stages**

For details on AND-type flash memory read and NAND-type flash memory read/program operation, see section 22.4.4, Command Access Mode.

### 22.4.2 Operating Modes

Two operating modes are supported.

- Command access mode
- Sector access mode

The ECC generation and error check are performed in sector access mode.

### 22.4.3 Register Setting Procedure

Figure 22.3 shows the register setting flow required for accessing the flash memory.

**Figure 22.3 Register Setting Flow**

22.4.4 Command Access Mode

Command access mode accesses flash memory by specifying a command to be issued to flash memory, address, data, read/write direction, and number of times to the registers. In this mode, I/O data can be transferred by the DMA via FLDTFIFO.

(1) AND-Type Flash Memory Access

Figures 22.4 and 22.5 show examples of read operation for AND-type flash memory. In these examples, the first command is specified as H'00 and address data length is specified as 2 bytes (SA1 and SA2). (Only SA1 and SA2 are specified, while CA1 and CA2 are not specified.). In addition, the number of read bytes is specified as 4 bytes in the data counter and H'FF is specified as the second command.

Figure 22.4 Read Operation Timing for AND-Type Flash Memory (1)

Figure 22.5 Read Operation Timing for AND-Type Flash Memory (2)

Figures 22.6 and 22.7 show examples of programming operation for AND-type flash memory.

**Figure 22.6 Programming Operation Timing for AND-Type Flash Memory (1)**

**Figure 22.7 Programming Operation Timing for AND-Type Flash Memory (2)**

## (2) NAND-Type Flash Memory Access

Figure 22.8 shows an example of read operation for NAND-type flash memory. In this example, the first command is specified as H'00, address data length is specified as 3 bytes, and the number of read bytes is specified as 8 bytes in the data counter.

**Figure 22.8 Read Operation Timing for NAND-Type Flash Memory (1)**

Figures 22.9 and 22.10 show examples of programming operation for NAND-type flash memory.

**Figure 22.9 Programming Operation Timing for NAND-Type Flash Memory (1)**

**Figure 22.10 Programming Operation Timing for NAND-Type Flash Memory (2)**

### (3) NAND-Type Flash Memory (2048 + 64 Bytes) Access

Figure 22.11 shows an example of read operation for NAND-type flash memory (2048 + 64 bytes). In this example, the first command is specified as H'00, the second command is specified as H'30, and address data length is specified as 4 bytes. The number of read bytes is specified as 4 bytes in the data counter.

**Figure 22.11 Read Operation Timing for NAND-Type Flash Memory**

Figures 22.12 and 22.13 show examples of programming operation for NAND-type flash memory (2048 + 64 bytes).

**Figure 22.12 Programming Operation Timing for NAND-Type Flash Memory (1)**

**Figure 22.13 Programming Operation Timing for NAND-Type Flash Memory (2)**

### 22.4.5 Sector Access Mode

In sector access mode, flash memory can be read or programmed in sector units by specifying the number of physical sectors to be accessed. In programming, an ECC is added. In read, an ECC error check (detection) is performed.

Since 512-byte data is stored in FLDTFIFO and 16-byte control code is stored in FLECFIFO, the DREQ1EN and DREQ0EN bits in FLINTDMACR can be set to transfer by the DMA.

Figure 22.14 shows the relationship of DMA transfer between sectors in flash memory (data and control code) and memory on the address space.

**Figure 22.14 Relationship between DMA Transfer and Sector (Data and Control Code), and Memory and DMA Transfer**

## (1) Physical Sector

Figure 22.15 shows the relationship between the physical sector address of AND/NAND-type flash memory and the address of flash memory.

**Figure 22.15 Relationship between Sector Number and Address Expansion of AND-/NAND-Type Flash Memory**

## (2) Continuous Sector Access

Continuous physical sectors can be read or written by specifying the start physical sector of NAND-type flash memory and the number of sectors to be transferred. Figure 22.16 shows an example of physical sector specification register and transfer count specification register settings when transferring logical sectors 0 to 40, which are not contiguous because of an unusable sector in NAND-type flash memory.

**Figure 22.16 Sector Access when Unusable Sector Exists in Continuous Sectors**

### 22.4.6 ECC Error Correction

The FLCTL generates and adds an ECC code during write operation in sector access mode and performs ECC error check during read operation in sector access mode. The FLCTL, however, does not perform error correction. Note that errors must be corrected by software.

### 22.4.7 Status Read

The FLCTL can read the status register of an AND-type or NAND-type flash memory. The data in the status register of an AND-type or NAND-type flash memory is input through the I/O7 to I/O0 pins and stored in the bits STAT[7:0] in FLBSYCNT. The bits STAT[7:0] in FLBSYCNT can be read by the CPU. If a program error or erase error is detected when the status register value is stored in the bits STAT[7:0] in FLBSYCNT, the STERB bit in FLINTDMACR is set to 1 and generates an interrupt to the CPU if the STERINTE bit in FLINTDMACR is enabled.

#### (1) Status Read of AND-Type Flash Memory

The status register of AND-type flash memory can be read by asserting the output enable signal  $\overline{OE}$  ( $\overline{OE} = 0$ ). If programming is executed in command access mode or sector access mode while the DOSR bit in FLCMDCR is set to 1, the FLCTL automatically asserts the  $\overline{OE}$  signal and reads the status register of AND-type flash memory. When the status register of AND-type flash memory is read, the I/O7 to I/O0 pins indicate the following information as described in table 22.3.

**Table 22.3 Status Read of AND-Type Flash Memory**

| I/O          | Status (definition) | Description                                       |
|--------------|---------------------|---------------------------------------------------|
| I/O7         | Ready/busy          | 0: Busy state<br>1: Ready state                   |
| I/O6         | Reserved            | —                                                 |
| I/O5         | Erase check         | 0: Pass (erased)<br>1: Fail (erase failure)       |
| I/O4         | Program check       | 0: Pass (programmed)<br>1: Fail (program failure) |
| I/O3 to I/O0 | Reserved            | —                                                 |

## (2) Status Read of NAND-Type Flash Memory

The status register of NAND-type flash memory can be read by inputting command H'70 to NAND-type flash memory. If programming is executed in command access mode or sector access mode while the DOSR bit in FLCMDCR is set to 1, the FLCTL automatically inputs command H'70 to NAND-type flash memory and reads the status register of NAND-type flash memory. When the status register of NAND-type flash memory is read, the I/O7 to I/O0 pins indicate the following information as described in table 22.4.

**Table 22.4 Status Read of NAND-Type Flash Memory**

| <b>I/O</b>   | <b>Status (definition)</b> | <b>Description</b>                              |
|--------------|----------------------------|-------------------------------------------------|
| I/O7         | Program protection         | 0: Cannot be programmed<br>1: Can be programmed |
| I/O6         | Ready/busy                 | 0: Busy state<br>1: Ready state                 |
| I/O5 to I/O1 | Reserved                   | —                                               |
| I/O0         | Program/erase              | 0: Pass<br>1: Fail                              |

## 22.5 Interrupt Sources

The FLCTL has six interrupt sources: Status error, ready/busy timeout error, ECC error, transfer end, FIFO0 transfer request, and FIFO1 transfer request. Each of the interrupt sources has its corresponding interrupt flag and the interrupt can be requested independently to the CPU if the interrupt is enabled by the interrupt enable bit. Note that the status error, ready/busy timeout error, and ECC error use the common FLSTE interrupt to the CPU.

**Table 22.5 FLCTL Interrupt Requests**

| Interrupt Source | Interrupt Flag | Enable Bit | Description              | Priority                    |
|------------------|----------------|------------|--------------------------|-----------------------------|
| FLSTE interrupt  | STERB          | STERINTE   | Status error             | Highest<br>↑<br>↓<br>Lowest |
|                  | BTOERB         | RBERINTE   | Ready/busy timeout error |                             |
|                  | ECERB          | ECERINTE   | ECC error                |                             |
| FLTEND interrupt | TREND          | TEINTE     | Transfer end             |                             |
| FLTRQ0 interrupt | TRREQF0        | TRINTE0    | FIFO0 transfer request   |                             |
| FLTRQ1 interrupt | TRREQF1        | TRINTE1    | FIFO1 transfer request   | Lowest                      |

## 22.6 DMA Transfer Specifications

The FLCTL can request DMA transfers separately to the data area FLDTFIFO and control code area FLECFIFO. Table 22.6 summarizes DMA transfer enable or disable states in each access mode.

**Table 22.6 DMA Transfer Specifications**

|          | <b>Sector Access Mode</b> | <b>Command Access Mode</b> |
|----------|---------------------------|----------------------------|
| FLDTFIFO | DMA transfer enabled      | DMA transfer enabled       |
| FLECFIFO | DMA transfer enabled      | DMA transfer disabled      |

In little endian form, these bits should not be used because a 16-byte DMA transfer causes a data replacement in longword units.

For details on DMAC settings, see section 10, Direct Memory Access Controller (DMAC).

## 22.7 Usage Notes

### (1) Usage Notes for the SNAND bit

When using the SNAND bit in FLCMNCR, only the first command or the second command is corresponded in spite of the setting of the DOCMD1 or DOCMD2 bit in FLCMDCR. When no command or only the first command is issued, 0 should be written in the SNAND bit.

## Section 23 USB 2.0 Host/Function Module (USB)

The USB 2.0 host/function module (USB) provides capabilities as a USB host and USB function and supports high-speed and full-speed transfers defined by USB specification 2.0. This module has a USB transceiver\* and supports all of the transfer types defined by the USB specification.

This module has an 8-kbyte buffer memory for data transfer, providing a maximum of eight pipes. Any endpoint numbers can be assigned to PIPE1 to PIPE7, based on the peripheral devices or user system for communication.

Note: \* The internal USB transceiver must be set before this module is used. For details, see section 23.5.2, Procedure for Setting the USB Transceiver.

### 23.1 Features

#### (1) Host Controller and Function Controller Supporting USB High-Speed Operation

- The USB host controller and USB function controller are incorporated.
- The USB host controller and USB function controller can be switched by register settings.
- Both high-speed transfer (480 Mbps) and full-speed transfer (12 Mbps) are supported.
- High-speed/full-speed USB transceiver (shared by the USB host and USB function) is incorporated.

#### (2) Reduced Number of External Pins and Space-Saving Installation

- On-chip D+ pull-up resistor (during USB function operation)
- On-chip D+ and D- pull-down resistor (during USB host operation)
- On-chip D+ and D- terminal resistor (during high-speed operation)
- On-chip D+ and D- output resistor (during full-speed operation)

#### (3) All Types of USB Transfers Supported

- Control transfer
- Bulk transfer
- Interrupt transfer (high bandwidth transfers not supported)
- Isochronous transfer (high bandwidth transfers not supported)

#### (4) Internal Bus Interfaces

- Two DMA interface channels are incorporated.

## (5) Pipe Configuration

- On-chip 8-kbyte buffer memory for USB communications
- Up to eight pipes can be selected (including the default control pipe)
- Programmable pipe configuration
- Endpoint numbers can be assigned flexibly to PIPE1 to PIPE7.
- Transfer conditions that can be set for each pipe:
  - PIPE0: Control transfer, continuous transfer mode, 256-byte fixed single buffer
  - PIPE1 and PIPE2: Bulk transfers/isochronous transfer, continuous transfer mode, programmable buffer size (up to 2-kbytes: double buffer can be specified)
  - PIPE3 to PIPE5: Bulk transfer, continuous transfer mode, programmable buffer size (up to 2-kbytes: double buffer can be specified)
  - PIPE6 and PIPE7: Interrupt transfer, 64-byte fixed single buffer

Note: When using isochronous OUT transfer, see section 23.5.1, Note on Using Isochronous OUT Transfer.

## (6) Features of the USB Host Controller

- Exclusive communication with a peripheral device with one-to-one connection
- Automatic scheduling for SOF and packet transmissions
- Programmable intervals for isochronous and interrupt transfers

## (7) Features of the USB Function Controller

- Control transfer stage control function
- Device state control function
- Auto response function for SET\_ADDRESS request
- NAK response interrupt function (NRDY)

## (8) Other Features

- Automatic recognition of high-speed operation or full-speed operation based on automatic response to the reset handshake
- Transfer ending function using transaction count
- DMA transfer termination function
- SOF interpolation function
- Zero-length packet addition function when ending DMA transfers (DEZPM)
- BRDY interrupt event notification timing change function (BFRE)

- Function that automatically clears the buffer memory after the data for the pipe specified at the DnFIFO (n = 0 or 1) port has been read (DCLRM)
- NAK setting function for response PID generated by end of transfer (SHTNAK)

## 23.2 Input/Output Pins

Table 23.1 shows the pin configuration and pin functions of the USB.

When this module is not in use, handle the pins as follows.

- Be sure to apply power to the power-supply pins
- Connect DP, DM, and VBUS to USBDPV<sub>ss</sub>
- Connect REFRIN to USBAPV<sub>cc</sub> through a 5.6 kΩ ± 20 % resistor
- For USB\_X1 and USB\_X2, see section 4.3, Clock Operating Modes

**Table 23.1 USB Pin Configuration**

| Category             | Name            | Pin Name | I/O   | Function                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-----------------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB bus interface    | USB D+ data     | DP       | I/O   | D+ I/O of the USB on-chip transceiver<br>This pin should be connected to the D+ pin of the USB bus.                                                                                                                                                                                                                                                                                                          |
|                      | USB D- data     | DM       | I/O   | D- I/O of the USB on-chip transceiver<br>This pin should be connected to the D- pin of the USB bus.                                                                                                                                                                                                                                                                                                          |
| VBUS monitor input   | VBUS input      | VBUS     | Input | USB cable connection monitor pin<br>This pin should be connected directly to the Vbus of the USB bus. Whether the Vbus is connected or disconnected can be detected.<br>If this pin is not connected with the Vbus of the USB bus, it should be supplied with 5 V. It should be supplied with 5 V also when the host controller function is selected.<br>Note: Vbus is not provided to the connected device. |
| Reference resistance | Reference input | REFRIN   | Input | Reference resistor connection pin<br>This pin should be connected to USBAPV <sub>ss</sub> through a 5.6 kΩ ±1% resistor.                                                                                                                                                                                                                                                                                     |

| Category     | Name                                        | Pin Name | I/O   | Function                                                                                                                |
|--------------|---------------------------------------------|----------|-------|-------------------------------------------------------------------------------------------------------------------------|
| Clock        | USB crystal oscillator/external clock       | USB_X1   | Input | These pins should be connected to crystal oscillators for the USB. The USB_X1 pin can be used for external clock input. |
|              |                                             | USB_X2   | Input |                                                                                                                         |
| Power supply | Transceiver block analog pin power supply   | USBAPVcc | Input | Power supply for pins                                                                                                   |
|              | Transceiver block analog pin ground         | USBAPVss | Input | Ground for pins                                                                                                         |
|              | Transceiver block digital pin power supply  | USBDPVcc | Input | Power supply for pins                                                                                                   |
|              | Transceiver block digital pin ground        | USBDPVss | Input | Ground for pins                                                                                                         |
|              | Transceiver block analog core power supply  | USBAVcc  | Input | Power supply for the core                                                                                               |
|              | Transceiver block analog core ground        | USBAVss  | Input | Ground for the core                                                                                                     |
|              | Transceiver block digital core power supply | USBDVcc  | Input | Power supply for the core                                                                                               |
|              | Transceiver block digital core ground       | USBDVss  | Input | Ground for the core                                                                                                     |

## 23.3 Register Description

Table 23.2 shows the register configuration of the USB.

**Table 23.2 Register Configuration**

| Register Name                         | Abbreviation | R/W | Initial Value | Address     | Access Size |
|---------------------------------------|--------------|-----|---------------|-------------|-------------|
| System configuration control register | SYSCFG       | R/W | H'0000        | H'FFFC 1C00 | 16          |
| System configuration status register  | SYSSTS       | R   | H'040x        | H'FFFC 1C02 | 16          |
| Device state control register         | DVSTCTR      | R/W | H'0000        | H'FFFC 1C04 | 16          |
| Test mode register                    | TESTMODE     | R/W | H'0100        | H'FFFC 1C06 | 16          |
| CPU-FIFO bus configuration register   | CFBCFG       | R/W | H'000F        | H'FFFC 1C0A | 16          |
| DMA0-FIFO bus configuration register  | D0FBCFG      | R/W | H'000F        | H'FFFC 1C0C | 16          |
| DMA1-FIFO bus configuration register  | D1FBCFG      | R/W | H'000F        | H'FFFC 1C0E | 16          |
| CFIFO port register                   | CFIFO        | R/W | H'00000000    | H'FFFC 1C10 | 8, 16, 32   |
| D0FIFO port register                  | D0FIFO       | R/W | H'00000000    | H'FFFC 1C14 | 8, 16, 32   |
| D1FIFO port register                  | D1FIFO       | R/W | H'00000000    | H'FFFC 1C18 | 8, 16, 32   |
| CFIFO port select register            | CFIFOSEL     | R/W | H'0000        | H'FFFC 1C1E | 16          |
| CFIFO port control register           | CFIFOCTR     | R/W | H'0000        | H'FFFC 1C20 | 16          |
| CFIFO port SIE register               | CFIFOSIE     | R/W | H'0000        | H'FFFC 1C22 | 16          |
| D0FIFO port select register           | D0FIFOSEL    | R/W | H'0000        | H'FFFC 1C24 | 16          |
| D0FIFO port control register          | D0FIFOCTR    | R/W | H'0000        | H'FFFC 1C26 | 16          |
| D0 transaction counter register       | D0FIFOTRN    | R/W | H'0000        | H'FFFC 1C28 | 16          |
| D1FIFO port select register           | D1FIFOSEL    | R/W | H'0000        | H'FFFC 1C2A | 16          |
| D1FIFO port control register          | D1FIFOCTR    | R/W | H'0000        | H'FFFC 1C2C | 16          |
| D1 transaction counter register       | D1FIFOTRN    | R/W | H'0000        | H'FFFC 1C2E | 16          |
| Interrupt enable register 0           | INTENB0      | R/W | H'0000        | H'FFFC 1C30 | 16          |
| Interrupt enable register 1           | INTENB1      | R/W | H'0000        | H'FFFC 1C32 | 16          |
| BRDY interrupt enable register        | BRDYENB      | R/W | H'0000        | H'FFFC 1C36 | 16          |
| NRDY interrupt enable register        | NRDYENB      | R/W | H'0000        | H'FFFC 1C38 | 16          |

| Register Name                             | Abbreviation | R/W | Initial Value | Address     | Access Size |
|-------------------------------------------|--------------|-----|---------------|-------------|-------------|
| BEMP interrupt enable register            | BEMPENB      | R/W | H'0000        | H'FFFC 1C3A | 16          |
| Interrupt status register 0               | INTSTS0      | R/W | H'00x0        | H'FFFC 1C40 | 16          |
| Interrupt status register 1               | INTSTS1      | R/W | H'0000        | H'FFFC 1C42 | 16          |
| BRDY interrupt status register            | BRDYSTS      | R/W | H'0000        | H'FFFC 1C46 | 16          |
| NRDY interrupt status register            | NRDYSTS      | R/W | H'0000        | H'FFFC 1C48 | 16          |
| BEMP interrupt status register            | BEMPSTS      | R/W | H'0000        | H'FFFC 1C4A | 16          |
| Frame number register                     | FRMNUM       | R/W | H'0000        | H'FFFC 1C4C | 16          |
| μFrame number register                    | UFRMNUM      | R/W | H'0000        | H'FFFC 1C4E | 16          |
| USB address register                      | USBADDR      | R   | H'0000        | H'FFFC 1C50 | 16          |
| USB request type register                 | USBREQ       | R   | H'0000        | H'FFFC 1C54 | 16          |
| USB request value register                | USBVAL       | R   | H'0000        | H'FFFC 1C56 | 16          |
| USB request index register                | USBINDX      | R   | H'0000        | H'FFFC 1C58 | 16          |
| USB request length register               | USBLENG      | R   | H'0000        | H'FFFC 1C5A | 16          |
| DCP configuration register                | DCPCFG       | R/W | H'0000        | H'FFFC 1C5C | 16          |
| DCP maximum packet size register          | DCPMAXP      | R/W | H'0040        | H'FFFC 1C5E | 16          |
| DCP control register                      | DCPCTR       | R/W | H'0040        | H'FFFC 1C60 | 16          |
| Pipe window select register               | PIPESEL      | R/W | H'0000        | H'FFFC 1C64 | 16          |
| Pipe configuration register               | PIPECFG      | R/W | H'0000        | H'FFFC 1C66 | 16          |
| Pipe buffer setting register              | PIPEBUF      | R/W | H'0000        | H'FFFC 1C68 | 16          |
| Pipe maximum packet size register         | PIPEMAXP     | R/W | H'0000        | H'FFFC 1C6A | 16          |
| Pipe cycle control register               | PIPEPERI     | R/W | H'0000        | H'FFFC 1C6C | 16          |
| Pipe 1 control register                   | PIPE1CTR     | R/W | H'0000        | H'FFFC 1C70 | 16          |
| Pipe 2 control register                   | PIPE2CTR     | R/W | H'0000        | H'FFFC 1C72 | 16          |
| Pipe 3 control register                   | PIPE3CTR     | R/W | H'0000        | H'FFFC 1C74 | 16          |
| Pipe 4 control register                   | PIPE4CTR     | R/W | H'0000        | H'FFFC 1C76 | 16          |
| Pipe 5 control register                   | PIPE5CTR     | R/W | H'0000        | H'FFFC 1C78 | 16          |
| Pipe 6 control register                   | PIPE6CTR     | R/W | H'0000        | H'FFFC 1C7A | 16          |
| Pipe 7 control register                   | PIPE7CTR     | R/W | H'0000        | H'FFFC 1C7C | 16          |
| USB AC characteristics switching register | USBACSWR     | R/W | H'00000000    | H'FFFC 1C84 | 32          |

### 23.3.1 System Configuration Control Register (SYSCFG)

SYSCFG is a register that enables high-speed operation, selects the host controller function or function controller function, controls the DP and DM pins, controls the full-speed receiver and controls a software reset for this module.

This register is initialized by a power-on reset.

### 23.3.2 System Configuration Status Register (SYSSTS)

SYSSTS is a register that monitors the line status (D+ and D– lines) of the USB data bus.

This register is initialized by a power-on reset, a software reset, or a USB bus reset.

| 1, 0 | LNST[1:0] | *             | R   | <p>USB Data Line Status</p> <p>Table 23.3 shows the USB data bus line status. The line status (D+ and D– lines) of the USB data bus is monitored using the setting of these bits.</p> <p>The line status can be confirmed with the full-speed receiver. This module automatically controls the full-speed receiver by supplying USBCLK. However, the full-speed receiver can be enabled using software, without supplying USBCLK, by setting the FSRPC bit in SYSCFG. After a power-on reset, D+ and D– line status can be confirmed prior to the USBCLK supply by setting the FSRPC bit to 1.</p> <p>Once USBCLK is supplied, software setting is not required.</p> |

Note: \* Depending on the D+ and D– line status.

**Table 23.3 USB Data Bus Line Status**

| LNST[1] | LNST[0] | During Full-Speed Operation | During High-Speed Operation | During Chirp Operation |
|---------|---------|-----------------------------|-----------------------------|------------------------|
| 0       | 0       | SE0                         | Squelch                     | Squelch                |
| 0       | 1       | J state                     | Not squelch                 | Chirp J                |
| 1       | 0       | K state                     | Invalid                     | Chirp K                |
| 1       | 1       | SE1                         | Invalid                     | Invalid                |

[Legend]

Chirp: The reset handshake protocol is being executed in high-speed operation enabled state (the HSE bit in SYSCFG is set to 1).

Squelch: SE0 or idle state

Not squelch: High-speed J state or high-speed K state

Chirp J: Chirp J state

Chirp K: Chirp K state

### 23.3.3 Device State Control Register (DVSTCTR)

DVSTCTR is a register that controls and confirms the state of the USB data bus.

This register is initialized by a power-on reset. After a software reset, WKUP is undefined but bits other than WKUP are initialized. After a USB bus reset, WKUP is initialized but RESUME is undefined.

| 1, 0 | RHST[1:0] | All 0         | R   | <p><b>Reset Handshake</b></p> <p>These bits are used to confirm the communication speed at which communication is being carried out with the host controller (communication bit rate).</p> <p>If the high-speed operation has been disabled (the HSE bit in SYSCFG is cleared to 0), this module establishes the full-speed operation without executing the reset handshake protocol. If the high-speed operation has been enabled (the HSE bit is set to 1), this module executes the reset handshake protocol (RHST = 01 during the execution) and feeds back the execution results to these bits (11 for high-speed operation, or 10 for full-speed operation).</p> <p>00: Communication speed not decided<br/> 01: Reset handshake is being handled<br/> 10: Full-speed operation established<br/> 11: High-speed operation established</p> <p>Note: If RHST is not established even though sufficient waiting time has elapsed after USB bus reset processing was complete (after setting USBRST = 0), the USB cable may have been disconnected during the USB bus reset processing. In this case, USB bus status should be checked with the LNST bits.</p> |

**Note:** When the function controller function is selected, the RWUPE, USBRST, RESUME and UACT bits must be cleared to 0.  
When the host controller function is selected, the WKUP bit must be cleared to 0.

### 23.3.4 Test Mode Register (TESTMODE)

TESTMODE is a register that controls the USB test signal output and the module's internal USB transceiver during high-speed operation. This register is initialized by a power-on reset. A software reset initializes the UTST bits.

### 23.3.5 FIFO Port Configuration Registers (CFBCFG, D0FBCFG, D1FBCFG)

CFBCFG, D0FBCFG, and D1FBCFG are registers that control FIFO port accesses. There are three FIFO ports; CPU-FIFO, DMA0-FIFO, and DMA1-FIFO. Accesses to these ports are controlled by the corresponding configuration registers.

These registers are initialized by a power-on reset.

### 23.3.6 FIFO Port Registers (CFIFO, D0FIFO, D1FIFO)

CFIFO, D0FIFO and D1FIFO are port registers that are used to read data from the FIFO buffer memory and writing data to the FIFO buffer memory.

There are three FIFO ports: the CFIFO, D0FIFO and D1FIFO ports. Each FIFO port is configured of a port register that handles reading of data from the buffer memory and writing of data to the buffer memory, a select register that is used to select the pipe assigned to the FIFO port, a control register, and registers used specially for port functions (an SIE register used exclusively for the CFIFO port and a transaction counter register used exclusively for the DnFIFO port).

These registers are initialized by a power-on reset or a software reset.

|---------|-----------------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | FIFOPORT [31:0] | All 0         | R/W | FIFO Port<br>These bits are used to read receive data from the buffer memory and write transmit data to the buffer memory. |

- Notes:
1. The DCP can access the buffer memory only through the CFIFO port. Accessing the buffer memory using DMA transfer can be performed only through the D0FIFO and D1FIFO ports.
  2. Accessing the DnFIFO port using the CPU must be performed in conjunction with the functions and restrictions of the DnFIFO port (using the transaction counter, etc.).
  3. When using functions specific to the FIFO port, the selected pipe cannot be changed (using the transaction counter, etc.).
  4. Registers configuring a FIFO port do not affect other FIFO ports.
  5. The same pipe should not be assigned to two or more FIFO ports.
  6. There are two sorts of buffer memory states: the access right is on the CPU side and it is on the SIE side. When the buffer memory access right is on the SIE side, the memory cannot be properly accessed from the CPU.
  7. The pipe configuration of the pipe selected for the FIFO port should not be changed.

### 23.3.7 FIFO Port Select Registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL)

CFIFOSEL, D0FIFOSEL and D1FIFOSEL are registers that assign the pipe to the FIFO port, and control access to the corresponding port.

The same pipe should not be specified by the CURPIPE bits in CFIFOSEL, D0FIFOSEL and D1FIFOSEL. When the CURPIPE bits in D0FIFOSEL and D1FIFOSEL are cleared to B'000, no pipe is selected.

The pipe number should not be changed while the DMA transfer is enabled.

These registers are initialized by a power-on reset or a software reset.

#### (1) CFIFOSEL

- Notes: 1. Only reading 0 and writing 1 are valid. Before setting REW to 1, confirm that FRDY is set to 1.
2. Changing the values of the CURPIPE bits in succession requires an access cycle lasting a minimum of 120 ns plus five bus cycles.

### 23.3.8 FIFO Port Control Registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR)

CFIFOCTR, D0FIFOCTR and D1FIFOCTR are registers that determine whether or not writing to the buffer memory has been finished, the buffer in the CPU has been cleared, and the FIFO port is accessible. CFIFOCTR, D0FIFOCTR, and D1FIFOCTR are used for the corresponding FIFO ports.

These registers are initialized by a power-on reset or a software reset.

| 11 to 0 | DTLN[11:0] | H'000         | R                 | <p>Receive Data Length*<sup>4</sup></p> <p>The length of the receive data can be confirmed.</p>                                                                                                                                                                                                                           |

- Notes:
1. Only 1 can be written to. Before setting BVAL to 1, confirm that FRDY is set to 1.
  2. Only reading 0 and writing 1 are valid.
  3. The BCLR bit is only valid for the buffer memory on the CPU side when a pipe other than DCP has been selected. Set BCLR to 1 after confirming that FRDY is 1. When DCP is selected as a pipe, the buffer memory on the SIE side is also cleared. In this case, confirming that FRDY = 1 is not necessary.
  4. The DTLN bits are only valid for the buffer memory on the CPU side. Confirm that FRDY = 1 before checking the DTLN bit.

### 23.3.9 FIFO Port SIE Register (CFIFOSIE)

CFIFOSIE is a register that controls the SIE functions of the CFIFO port. This register switches the access right between the SIE and CPU, clears the SIE buffer memory, and checks whether the SIE buffer is busy or not. This register is not operational when DCP is selected.

This register is initialized by a power-on reset and a software reset.

### 23.3.10 Transaction Counter Registers (D0FIFOTRN, D1FIFOTRN)

D0FIFOTRN and D1FIFOTRN are registers that are used to set the number of DMA transfer transactions and read the number of transactions.

These registers are initialized by a power-on reset and a software reset.

### 23.3.11 Interrupts Enable Register 0 (INTENB0)

INTENB0 is a register that specifies the interrupt masks. The URST, SADR, SCFG and SUSP bits operate as interrupt mask bits for the device state transition interrupt sources. The WDST, RDST, CMPL and SERR bits operate as interrupt mask bits for the control transfer stage interrupt sources.

This register is initialized by a power-on reset or a software reset.

Note: After the interrupt status was cleared, an interval of 80 ns or more is required before enabling/disabling the corresponding interrupt.

### 23.3.12 Interrupt Enabled Register 1 (INTENB1)

INTENB1 is a register that specifies the masking of various interrupts and controls the BRDYM interrupt status clear timing.

This register is initialized by a power-on reset. By a software reset, bits other than BRDYM are initialized.

### 23.3.13 BRDY Interrupts Enable Register (BRDYENB)

BRDYENB is a register that enables BRDY interrupts for each pipe.

This register is initialized by a power-on reset or a software reset.

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7              | 6              | 5              | 4              | 3              | 2              | 1              | 0              |

Note: If an interrupt is enabled/disabled after the interrupt status was cleared, an interval of 80 ns or more is required.

### 23.3.14 NRDY Interrupt Enable Register (NRDYENB)

NRDYENB is a register that enables NRDY interrupts for each pipe.

This register is initialized by a power-on reset or a software reset.

Note: If an interrupt is enabled/disabled after the interrupt status was cleared, an interval of 80 ns or more is required.

### 23.3.15 BEMP Interrupt Enabled Register (BEMPENB)

BEMPENB is a register that enables BEMP interrupts for each pipe.

This register is initialized by a power-on reset or a software reset.

**Note:** If an interrupt is enabled/disabled after the interrupt status was cleared, an interval of 80 ns or more is required.

### 23.3.16 Interrupt Status Register 0 (INTSTS0)

INTSTS0 is a register that is used to confirm interrupt statuses.

This register is initialized by a power-on reset or a software reset. By a USB bus reset, the DVSQ2 to DVSQ0 bits are initialized.

- Notes:
1. Only 0 can be written to.
  2. If multiple sources have occurred among the VBINT, RESM, SOFR, DVST, and CTRT bits, an access cycle of at least 140 ns and 3 bus clock cycles is required in order to clear the bits in succession, not simultaneously.
  3. This bit is initialized to 1 when the VBUS pin is high level and 0 when it is low level.
  4. These bits are initialized to B'000 by a power-on reset or a software reset, and B'001 by a USB bus reset.

### 23.3.17 Interrupt Status Register 1 (INTSTS1)

INTSTS1 is a register that is used to confirm interrupt status. The SOFR, BEMP, NRDY and BRDY bits are mirror bits of INTSTS0. When these bits are read, the corresponding bit values in INTSTS0 will be read. When these bits in INTSTS1 are written to, the written values are also reflected in INTSTS0.

Interrupt generation can be confirmed simply by referencing one of the registers: INTSTS0 when the peripheral controller function is selected and INTSTS1 when the host controller function is selected.

This register is initialized by a power-on reset or a software reset.

### 23.3.18 BRDY Interrupt Status Register (BRDYSTS)

BRDYSTS is a register that is used to confirm the BRDY interrupt status for each pipe.

This register is initialized by a power-on reset or a software reset.

Notes: 1. Only 0 can be written to.  
2. If multiple sources have occurred, an access cycle of at least 140 ns and 3 bus clock cycles is required in order to clear the bits in succession, not simultaneously.

### 23.3.19 NRDY Interrupt Status Register (NRDYSTS)

NRDYSTS is a register that is used to confirm the NRDY interrupt status for each pipe.

This register is initialized by a power-on reset or a software reset.

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7             | 6             | 5             | 4             | 3             | 2             | 1             | 0             |

Notes: 1. Only 0 can be written to.  
2. If multiple sources have occurred, an access cycle of at least 140 ns and 3 bus clock cycles is required in order to clear the bits in succession, not simultaneously.

### 23.3.20 BEMP Interrupt Status Register (BEMPSTS)

BEMPSTS is a register that is used to confirm the BEMP interrupt status for each pipe.

This register is initialized by a power-on reset or a software reset.

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7             | 6             | 5             | 4             | 3             | 2             | 1             | 0             |

Notes: 1. Only 0 can be written to.  
 2. If multiple sources have occurred, an access cycle of at least 140 ns and 3 bus clock cycles is required in order to clear the bits in succession, not simultaneously.

### 23.3.21 Frame Number Register (FRMNUM)

FRMNUM is a register that determines the source of isochronous error notification, selects SOFR interrupt operating mode, and indicates the frame number.

This register is initialized by a power-on reset or a software reset.

|                |       |       |    |    |       |            |   |   |   |   |   |   |   |   |   |   |

If the module cannot detect an SOF packet because the packet has been corrupted or for other reasons, the FRNM value is retained until a new SOF packet is received.</p> <p>The FRNM bit based on the SOF interpolation timer is not updated.</p>                                                                                                                                                                                                                                              |

Notes: 1. Only 0 can be written to.  
 2. If OVRN and CRCE sources have occurred, an access cycle of at least 140 ns and 3 bus clock cycles is required in order to clear the bits in succession, not simultaneously.

**Table 23.8 Error Information When NRDY Interrupt is Generated in Isochronous OUT Transfer**

| Bit Status | Generating Timing         | Generating Conditions                                                       | Detected Error              | Operation                 |
|------------|---------------------------|-----------------------------------------------------------------------------|-----------------------------|---------------------------|
| OVRN = 1   | A data packet is received | A new data packet is received before reading of buffer memory is completed. | Receive data buffer overrun | Receive data is discarded |
| CRCE = 1   | A data packet is received | A CRC error or a bit stuffing error is detected.                            | Receive packet error        | Receive data is discarded |

**Table 23.9 Error Information When NRDY Interrupt is Generated in Isochronous IN Transfer**

| Bit Status | Issued When          | Issue Conditions                                                      | Detected Error                | Operation                         |
|------------|----------------------|-----------------------------------------------------------------------|-------------------------------|-----------------------------------|
| OVRN = 1   | IN-token is received | An IN-token is received before writing to buffer memory is completed. | Transmit data buffer underrun | Zero-length packet is transmitted |
| CRCE = 1   | Not generated        | —                                                                     | —                             | —                                 |

**23.3.22  $\mu$ Frame Number Register (UFRMNUM)**

UFRMNUM is a register that indicates the  $\mu$ frame number.

This register is initialized by a power-on reset or a software reset.

23.3.23 USB Address Register (USBADDR)

USBADDR is a register that indicates the USB address. This register is valid only when the function controller function is selected. When the host controller function is selected, peripheral addresses should be set using the DEVSEL bits in PIPEMAXP.

This register is initialized by a power-on reset, a software reset, or a USB bus reset.

|                |    |    |    |    |    |    |   |   |   |              |   |   |   |   |   |   |
|----------------|----|----|----|----|----|----|---|---|---|--------------|---|---|---|---|---|---|

| Bit     | Bit Name      | Initial Value | R/W | Description                                                                      |
|---------|---------------|---------------|-----|----------------------------------------------------------------------------------|
| 15 to 7 | —             | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 6 to 0  | USBADDR [6:0] | H'00          | R   | USB Address<br>These bits indicate the USB address.                              |

### 23.3.24 USB Request Type Register (USBREQ)

USBREQ is a register that stores setup requests for control transfers. When the function controller function is selected, the values of bRequest and bmRequestType that have been received are stored. When the host controller function is selected, the values of bRequest and bmRequestType to be transmitted are set.

This register is initialized by a power-on reset, software reset, or a USB bus reset.

|                |               |     |     |     |     |     |     |     |                    |     |     |     |     |     |     |     |
|----------------|---------------|-----|-----|-----|-----|-----|-----|-----|--------------------|-----|-----|-----|-----|-----|-----|-----|

| Bit     | Bit Name                | Initial Value | R/W  | Description                                                           |
|---------|-------------------------|---------------|------|-----------------------------------------------------------------------|
| 15 to 8 | BREQUEST [7:0]          | H'00          | R/W* | Request<br>These bits store the USB request bRequest value.           |
| 7 to 0  | BMREQUEST-<br>TYPE[7:0] | H'00          | R/W* | Request Type<br>These bits store the USB request bmRequestType value. |

Note: \* When the function controller function is selected, these bits can only be read. When the host controller function is selected, these bits can be read and written to.

23.3.25 USB Request Value Register (USBVAL)

USBVAL is a register that stores setup requests for control transfers. When the peripheral controller function is selected, the value of wValue that has been received is stored. When the host controller function is selected, the value of wValue to be transmitted is set.

This register is initialized by a power-on reset, a software reset, or a USB bus reset.

| Bit     | Bit Name     | Initial Value | R/W  | Description                                             |
|---------|--------------|---------------|------|---------------------------------------------------------|
| 15 to 0 | WVALUE[15:0] | H'0000        | R/W* | Value<br>These bits store the USB request wValue value. |

Note: \* When the function controller function is selected, these bits can only be read. When the host controller function is selected, these bits can be read or written to.

23.3.26 USB Request Index Register (USBINDX)

USBINDEX is a register that stores setup requests for control transfers. When the function controller function is selected, the value of wIndex that has been received is stored. When the host controller function is selected, the value of wIndex to be transmitted is set.

This register is initialized by a power-on reset, software reset, or a USB bus reset.

| Bit     | Bit Name     | Initial Value | R/W  | Description                                             |
|---------|--------------|---------------|------|---------------------------------------------------------|
| 15 to 0 | WINDEX[15:0] | H'0000        | R/W* | Index<br>These bits store the USB request wIndex value. |

Note: \* When the function controller function is selected, these bits can only be read. When the host controller function is selected, these bits can be read or written to.

23.3.27 USB Request Length Register (USBLENG)

USBLENG is a register that stores setup requests for control transfers. When the peripheral controller function is selected, the value of wLength that has been received is stored. When the host controller function is selected, the value of wLength to be transmitted is set.

This register is initialized by a power-on reset, a software reset, and a USB bus reset.

| Bit     | Bit Name       | Initial Value | R/W  | Description                                               |
|---------|----------------|---------------|------|-----------------------------------------------------------|
| 15 to 0 | WLENGTH [15:0] | H'0000        | R/W* | Length<br>These bits store the USB request wLength value. |

Note: \* When the function controller function is selected, these bits can only be read. When the host controller function is selected, these bits can be read or written to.

### 23.3.28 DCP Configuration Register (DCPCFG)

DCPCFG is a register that selects continuous transfer mode or non-continuous transfer mode, the data transfer direction, and whether to continue or disable the DCP pipe operation at the end of transfer for the default control pipe (DCP).

This register is initialized by a power-on reset or a software reset.

|                |    |    |    |    |    |    |   |       |            |   |   |     |   |   |   |   |

### 23.3.29 DCP Maximum Packet Size Register (DCPMAXP)

DCPMAXP is a register that specifies the maximum packet size for the DCP.

This register is initialized by a power-on reset or a software reset.

Note: \* Writing to MXPS[2:0] is invalid.

### 23.3.30 DCP Control Register (DCPCTR)

DCPCTR is a register that is used to confirm the buffer memory status, change and confirm the data PID sequence bit, and set the response PID for the DCP.

This register is initialized by a power-on reset or a software reset. The CCPL and PID[2:0] bits are initialized by a USB bus reset.

If a transfer error is detected, the controller sets these bits to end the transfer. |

- Notes:
1. This bit is valid only when 0 is read.
  2. This bit is valid only when 1 is written to.
  3. The SQCLR SQSET bits should not be set to 1 at the same time. Before operating either bit, PID = NAK should be set.
  4. To change the SQSET or SQCLR bit in this register and that in PIPEnCTR in succession (to change the PID sequence toggle bits of multiple pipes in succession), an access cycle of at least 120 ns and 5 or more bus clock cycles is required.

### 23.3.31 Pipe Window Select Register (PIPESEL)

PIPESEL is a register that selects the pipe to be used among PIPE1 to PIPE7. After selecting the pipe, functions of the pipe should be set using PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI. PIPEnCTR can be set regardless of the pipe selection in PIPESEL.

For a power-on reset, a software reset and a USB bus reset, the corresponding bits for not only the selected pipe but all of the pipes are initialized.

This register is initialized by a power-on reset or a software reset.

### 23.3.32 Pipe Configuration Register (PIPECFG)

PIPECFG is a register that specifies the transfer type, buffer memory access direction, and endpoint numbers for PIPE1 to PIPE7. It also selects continuous or non-continuous transfer mode, single or double buffer mode, and whether to continue or disable pipe operation at the end of transfer.

This register is initialized by a power-on reset or a software reset. Only the TYPE1 and TYPE0 bits are initialized by a USB bus reset.

Note: \* When using isochronous OUT transfer, see section 23.5.1, Note on Using Isochronous OUT Transfer.

### 23.3.33 Pipe Buffer Setting Register (PIPEBUF)

PIPEBUF is a register that specifies the buffer size and buffer number for PIPE1 to PIPE7.

This register is initialized by a power-on reset or a software reset.

### 23.3.34 Pipe Maximum Packet Size Register (PIPEMAXP)

PIPEMAXP is a register that specifies the maximum packet size for PIPE1 to PIPE7.

This register is initialized by a power-on reset or a software reset.

Note: \* The initial value of MXPS is H'000 when no pipe is selected with the PIPESEL bits in PIPESEL and H'040 when a pipe is selected with the PIPESEL bit in PIPESEL.

### 23.3.35 Pipe Timing Control Register (PIPEPERI)

PIPEPERI is a register that selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfer, and sets the interval error detection interval for PIPE1 and PIPE2.

This register is initialized by a power-on reset or a software reset.

### 23.3.36 PIPEn Control Registers (PIPEnCTR) (n = 1 to 7)

PIPEnCTR is a register that is used to confirm the buffer memory status for the corresponding pipe, change and confirm the data PID sequence bit, determine whether the auto response mode is set, determine whether the auto buffer clear mode is set, and set a response PID. This register can be set regardless of the pipe selection in PIPESEL.

This register is initialized by a power-on reset or a software reset. PID[1:0] are initialized by a USB bus reset.

| 5 to 2 | —        | All 0         | R                 | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                                                                                                                                                                                      |
| 1, 0   | PID      | 00            | R/W               | Response PID <sup>*3</sup><br>00: NAK response<br>01: BUF response (depending on the buffer state)<br>10: STALL response<br>11: STALL response<br>When the host controller function is selected and PID is not set to BUF, no token is issued. If a transfer error is detected, the controller sets the PID bits to end the transfer. |

- Notes:
1. Reading of 0 and writing of 1 are valid.
  2. If the SQCLR and SQSET bits in this register and DCPCTR are being used to change the data PID sequence toggle bit for several pipes in succession, an access cycle of 120 ns and 5- or more bus clock cycles is required.
  3. The SQCLR bit and SQSET bits should not be set to 1 at the same time. Before operating either bit, PID = NAK should be set. If isochronous transfer is set for the transfer type (TYPE = 11), writing to the SQSET bit is invalid.

### 23.3.37 USB AC Characteristics Switching Register (USBACSWR)

USBACSWR is used to set for the internal USB transceiver of this module.

This register is initialized by a power-on reset.

## 23.4 Operation

### 23.4.1 System Control

This section describes the register operations that are necessary to the initial settings of this module, and the registers necessary for power consumption control.

#### (1) Resets

Table 23.10 lists the types of controller resets. For the initialized states of the registers following the reset operations, see section 23.3, Register Description.

**Table 23.10 Types of Reset**

| Name           | Operation                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------|
| Power-on reset | Low level input from the $\overline{\text{RES}}$ pin                                                             |
| Software reset | Operation using the USBE bit in SYSCFG                                                                           |
| USB bus reset  | Automatically detected by this module from the D+ and D– lines when the function controller function is selected |

#### (2) Controller Function Selection

This module can select the host controller function or function controller function using the DCFM bit in SYSCFG.

#### (3) Enabling High-Speed Operation

This module can select a USB communication speed (communication bit rate) of either high-speed or full-speed using software. In order to enable the high-speed operation for this module, the HSE bit in SYSCFG should be set to 1. Changing the HSE bit should be done in the initial settings immediately after a power-on reset or with the D+ line pull-up disabled (DPRPU = 0).

If high-speed mode has been enabled, this module executes the reset handshake protocol, and the USB communication speed is set automatically. The results of the reset handshake can be confirmed using the RHST bit in DVSTCTR.

If high-speed operation has been disabled, this module operates at full-speed.

#### (4) USB Data Bus Resistor Control

Figure 23.1 shows a diagram of the connections between this module and the USB connectors.

This module incorporates a pull-up resistor for the D+ signal and a pull-down resistor for the D+ and D- signals. These signals can be pulled up or down using the DPRPU and DMRPD bits in SYSCFG.

This module controls the terminal resistor for the D+ and D- signals during high-speed operation and the output resistor for the signals during full-speed operation. This module automatically switches the resistor after connection with the host controller or peripheral device by means of reset handshake, suspended state and resume detection. If a disconnection from the host controller or peripheral device is detected, this module should be initialized by a software reset.

When the function controller function is selected and the DPRPU bit in SYSCFG is cleared to 0 during communication with the host controller, the pull-up resistor (or the terminal resistor) of the USB data line is disabled, making it possible to control the device connection and disconnection using software with the USB cable being connected.

**Figure 23.1 UBS Connector Connection**

### 23.4.2 Interrupt Functions

Table 23.11 lists the interrupt generation conditions for this module.

When an interrupt generation condition is satisfied and the interrupt output is enabled using the corresponding interrupt enable register, this module outputs the USB interrupt request signal to the INTC.

**Table 23.11 Interrupt Generation Conditions**

| Bit   | Interrupt Name                | Cause of Interrupt                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Function That Generates the Interrupt | Related Status |
|-------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|----------------|
| VBINT | VBUS interrupt                | When a change in the state of the VBUS input pin has been detected (low to high or high to low)                                                                                                                                                                                                                                                                                                                                                                                 | Host, function                        | VBSTS          |
| RESM  | Resume interrupt              | When a change in the state of the USB bus has been detected in the suspended state (J-state to K-state or J-state to SE0)                                                                                                                                                                                                                                                                                                                                                       | Function                              | —              |
| SOFR  | Frame number update interrupt | When the host controller function is selected: <ul style="list-style-type: none"> <li>When an SOF packet with a different frame number has been transmitted</li> </ul> When the function controller function is selected: <ul style="list-style-type: none"> <li>SOFRM = 0: When an SOF packet with a different frame number is received</li> <li>SOFRM = 1: When the SOF with the <math>\mu</math>frame number 0 cannot be received due to a corruption of a packet</li> </ul> | Host, function                        | —              |

| Bit  | Interrupt Name                              | Cause of Interrupt                                                                                                                                                                                                                                                                                                                               | Function That Generates the Interrupt | Related Status       |

Note: \* It is recognized as “no response” when no SYNC field is detected within a specified duration.

Figure 23.2 shows a diagram relating to interrupts of this module.

**Figure 23.2 Items Relating to Interrupts**

## (1) BRDY Interrupt

The BRDY interrupt is generated when either of the host controller function or function controller function is selected. Table 23.12 shows the conditions under which this module sets 1 to a corresponding bit in BRDYSTS. Under this condition, this module generates BRDY interrupt, if software sets the PIPEBRDYE bit in BRDYENB that corresponds to the pipe to 1 and the BRDYE bit in INTENB0 to 1. Figure 23.3 shows the timing at which the BRDY interrupt is generated.

The conditions for clearing the BRDY bit in INTSTS0 by this module depend on the setting of the BRDYM bit in INTENB1. Table 23.13 shows the conditions.

When the function controller function is selected, under condition 1 noted below, a zero-length packet is always transmitted for an IN token, and the BRDY interrupt is not generated.

1. When the transfer type is set to bulk IN transfer, PID is set to BUF, and the ATREPM bit in PIPEnCTR is set to H'01.

**Table 23.12 Conditions under which a BRDY Interrupt is Generated**

| Access Direction | Transfer Direction | Pipe   | BFRE | DBLB | Conditions under which BRDY Interrupt is Generated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Note: \* In non-continuous transfer (CNTMD = 0), “buffer full” means that the maximum packet size of data has been received. In continuous transfer (CNTMD = 1), it means that the buffer size of data has been received.

If a zero-length packet has been received, the corresponding bit in BRDYSTS is set to 1 but data in the corresponding packet cannot be read. The buffer should be cleared (BCLR = 1) after clearing BRDYSTS.

With PIPE1 to PIPE7, if DMA transfer is performed in the reading direction, interrupts can be generated in transfer units, by setting the BFRE bit in PIPECFG to 1.

**Figure 23.3 Timing at which a BRDY Interrupt Is Generated**

**Table 23.13 Conditions for Clearing the BRDY Bit**

| BRDYM | Conditions for Clearing the BRDY Bit                                                           |
|-------|------------------------------------------------------------------------------------------------|
| 0     | When software clears all of the bits in BRDYSTS, this module clears the BRDY bit in INSTS0.    |
| 1     | When the BTST bits for all pipes are cleared to 0, this module clears the BRDY bit in INTSTS0. |

## (2) NRDY Interrupt

If a pipe is under the conditions below, this module sets the corresponding bit in NRDYSTS to 1. In this case, this module issues the NRDY interrupt if software sets the PIPENRDYE bit in NRDYENB corresponding to the pipe and the NRDYE bit in INTENB0 to 1. When software clears all the bits in NRDYSTS, this module clears the NRDY bit in INTSTS0.

### (a) When the host controller function is selected:

The NRDY interrupt is generated under either of the following conditions. At this time, hardware sets the PID bits to stop issuing a token. For the operation of the PID bits, see section 23.4.3 (4), Response PID.

- STALL has been received from the peripheral side for the issued token.
- No response has been returned from the peripheral side for the issued token.

Note: It is recognized as “no response” when no SYNC field is detected within a specified duration.

- An overrun/underrun error has occurred during isochronous transfer.

However, a SIGN interrupt will be generated when no ACK response has been returned from the peripheral side in setup transaction.

### (b) When the function controller function is selected:

The NRDY interrupt is generated under the following conditions.

#### 1. For data transmission

If an IN token has been received (data underrun) when the PID bit in PIPEnCTR is set to BUF and there are no data waiting to be transmitted in the buffer memory.

#### 2. For data reception

- If an OUT token or PING token has been received (data overrun) when the PID bit in PIPEnCTR is set to BUF and there are no area in the buffer memory where data can be stored.
- In a bulk transfer, when the maximum packet size has not been set (MXPS = 0) and an OUT token or a PINK token has been received
- When a CRC error or bit stuffing error has occurred during isochronous transfer
- In an isochronous transfer, when a token has been received in a period other than the interval frame (an interval error).

Figure 23.4 shows the timing at which an NRDY interrupt is generated when the function controller function is selected.

**Figure 23.4 Timing at which NRDY Interrupt Is Generated when Function Controller Function is Selected**

### (3) BEMP Interrupt

If a pipe is under the conditions below, this module sets the corresponding bit in BEMPSTS to 1. In this case, this module generates a BEMP interrupt if software sets the PIPEBEMPE bit in BEMPENB corresponding to the corresponding pipe and the BEMPE bit in INTENB0 to 1. If software clears all the bits in BEMPSTS, this module clears the BEMP bit in INTSTS0.

1. When the transmitting direction (writing to the buffer memory) has been set  
 When all of the data stored in the buffer memory has been transmitted  
 If the buffer memory is being used as a double buffer, however, the following conditions should be met.
  - A BEMP interrupt is generated if the buffer on one side is empty and transmitting of data from the buffer on the other side has been completed.
  - A BEMP interrupt is generated if data consisting of less than eight bytes is being written to the buffer on one side, and transmitting of data from the buffer on the other side has been completed. However, when the writing ended by setting BVAL to 1, no BEMP interrupt is generated even if the data write consists of less than eight bytes.
2. When the receiving direction (reading from the buffer memory) has been set  
 If the size of the data packet that was received exceeded the maximum packet size and the maximum packet size is not set to 0 (MXPS  $\neq$  0), this module sets the PID bit of the corresponding pipe to STALL.

Figure 23.5 shows the timing at which a BEMP interrupt is generated when the function controller function has been selected.

**Figure 23.5 Timing at which BEMP Interrupt Is Generated when Function Controller Function is Selected**

#### (4) Device State Transition Interrupt

Figure 23.6 shows a diagram of this module device state transitions. This module controls device states and generates device state transition interrupts. However, recovery from the suspended state (resume signal detection) is detected by means of the resume interrupt. The device state transition interrupts can be enabled or disabled individually using INTENB0. The device state that made a transition can be confirmed using the DVSQ bit in INTSTS0.

To make a transition to the default state, the device state transition interrupt is generated after the reset handshake protocol has been completed.

Device state can be controlled only when the function controller function is selected. Also, the device state transition interrupts can be generated only when the function controller function is selected.

Figure 23.6 Device State Transitions

## (5) Control Transfer Stage Transition Interrupt

Figure 23.7 shows a diagram of how this module handles the control transfer stage transition. This module controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled individually using INTENB0. The transfer stage that made a transition can be confirmed using the CTSQ bit in INTSTS0.

The control transfer sequence errors are described below. If an error occurs, the PID bit in DCPCTR is set to B'1x (STALL).

1. During control read transfers
  - At the IN token of the data stage, an OUT or PING token is received when there have been no data transfers at all.
  - An IN token is received at the status stage
  - A packet is received at the status stage for which the data packet is DATAPID = DATA0
2. During control write transfers
  - At the OUT token of the data stage, an IN token is received when there have been no ACK response at all
  - A packet is received at the data stage for which the first data packet is DATAPID = DATA0
  - At the status stage, an OUT or PING token is received
3. During no-data control transfers
  - At the status stage, an OUT or PING token is received

At the control write transfer stage, if the number of receive data exceeds the wLength value of the USB request, it cannot be recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (SERR = 1), the CTSQ = 110 value is retained until CTRT = 0 is written from the system (the interrupt status is cleared). Therefore, while CTSQ = 110 is being held, the CTRT interrupt that ends the setup stage will not be generated even if a new USB request is received. (This module retains the setup stage end, and after the interrupt status has been cleared by software, CTRT interrupt is generated.)

**Figure 23.7 Control Transfer Stage Transitions**

## (6) Frame Update Interrupt

Figure 23.8 shows an example of the SOFR interrupt output timing of this module. When the frame number is updated or a damaged SOF packet is detected, the SOFR interrupt is generated. The interrupt operation should be specified using the SOFRM bit in FRMNUM.

When the host controller function is selected, SOFRM = 1 should not be set.

### 1. When SOFRM = 0 is set

The SOFR interrupt is generated when the frame number is updated (intervals of approximately 1 ms). Interrupts are generated by the internal interpolation function even if an SOF packet is damaged or missing. During high-speed communication, interrupts are generated at the timing at which the frame number is updated (intervals of approximately 1 ms).

## 2. When SOFRM = 1 is set

The SOFR interrupt is generated when SOF packets are damaged or missing. During high-speed communication, interrupts are generated only if the first packet of a  $\mu$ SOF packet with the same frame number is damaged or missing. (Corrupted or missing SOFs are recognized by the SOF interpolation function. For details, see section 23.4.9, SOF Interpolation Function.)

When the function controller function is selected, this module updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation. During high-speed operation, however, this module does not update the frame number, or generates no SOFR interrupt until the module enters the  $\mu$ SOF locked state. Also, the SOF interpolation function is not activated. The  $\mu$ SOF lock state is the state in which  $\mu$ SOF packets with different frame numbers are received twice continuously without error occurrence.

The conditions under which the  $\mu$ SOF lock monitoring begins and stops are as follows.

### 1. Conditions under which $\mu$ SOF lock monitoring begins

USBE = 1

### 2. Conditions under which $\mu$ SOF lock monitoring stops

USBE = 0 (software reset), a USB bus reset is received, or suspended state is detected.

**Figure 23.8 Example of SOFR Interrupt Output Timing**

### **(7) VBUS Interrupt**

If there has been a change in the VBUS pin, the VBUS interrupt is generated. The level of the VBUS pin can be checked with the VBSTS bit in INTSTS0. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. However, if the system is activated with the host controller connected, the first VBUS interrupt is not generated because there is no change in the VBUS pin.

### **(8) Resume Interrupt**

The RESM interrupt is generated when the device state is the suspended state, and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the suspended state is detected by means of the resume interrupt.

### **(9) BCHG Interrupt**

The BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether or not the function device is connected when the host controller function has been selected and can also be used to detect a remote wakeup. The BCHG interrupt is generated regardless of whether the host controller function or function controller function has been selected.

### **(10) DTCH Interrupt**

The DTCH interrupt is generated if disconnection of the device is detected during full-speed operation when the host controller function has been selected. The DTCH interrupt is detected when SE0 = 25  $\mu$ s or more. Note that the DTCH interrupt cannot be used in high-speed mode. Clear DTCHE to 0 in high-speed mode. To detect disconnection during high-speed operation, additional processing is necessary, such as performing periodic control transfers of standard requests and determining disconnection if no response is returned from the peripheral side.

As a specific example, disconnection can be recognized when, after issuing a set configuration request, no response is received from a peripheral after a get status request.

### **(11) SACK Interrupt**

The SACK interrupt is generated when an ACK response for the transmitted setup packet has been received from the peripheral side with the host controller function selected. The SACK interrupt can be used to confirm that the setup transaction has been completed successfully.

## (12) SIGN Interrupt

The SIGN interrupt is generated when an ACK response for the transmitted setup packet has not been received from the peripheral side with the host controller function selected. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral side or corruption of an ACK packet.

Note: It is recognized as “no response” when no SYNC field is detected within a specified duration.

### 23.4.3 Pipe Control

Table 23.14 lists the pipe setting items of this module. With USB data transfer, data transmission has to be carried out using the logic pipe called the endpoint. This module has eight pipes that are used for data transfer.

Settings should be entered for each of the pipes in conjunction with the specifications of the system.

**Table 23.14 Pipe Setting Items**

| Register Name     | Bit Name | Setting Contents                                       | Remarks                                                                                                                                                                                                                                       |

|                     | SQMON    | Sequence confirm                                   | Confirms the data toggle bit                                                                                                                                                          |
|                     | PID      | Response PID                                       | See section 23.4.3 (4), Response PID                                                                                                                                                  |

## (1) Transfer Types

The TYPE bit in PIPECFG is used to specify the transfer type for each pipe. The transfer types that can be set for the pipes are as follows.

1. DCP: No setting is necessary (fixed at control transfer).
2. PIPE1 and PIPE2: These should be set to bulk transfer or isochronous transfer.
3. PIPE3 to PIPE5: These should be set to bulk transfer.
4. PIPE6 and PIPE7: These should be set to interrupt transfer.

## (2) Endpoint Number

The EPNUM bit in PIPECFG is used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to endpoint 15.

1. DCP: No setting is necessary (fixed at end point 0).
2. PIPE1 to PIPE7: The endpoint numbers from 1 to 15 should be selected and set.  
These should be set so that the combination of the DIR bit and EPNUM bit is unique.

## (3) Maximum Packet Size Setting

The MXPS bit in DCPMAXP and PIPEMAXP is used to specify the maximum packet size for each pipe. DCP and PIPE1 to PIPE5 can be set to any of the maximum pipe sizes defined by the USB specification. For PIPE6 and PIPE7, 64 bytes are the upper limit of the maximum packet size. The maximum packet size should be set before beginning the transfer (PID = BUF).

1. DCP: 64 should be set when using high-speed operation.
2. DCP: Select and set 8, 16, 32, or 64 when using full-speed operation.
3. PIPE1 to PIPE5: 512 should be set when using high-speed bulk transfer.
4. PIPE1 to PIPE5: Select and set 8, 16, 32, or 64 when using full-speed bulk transfer.
5. PIPE1 and PIPE2: Set a value between 1 and 1024 when using high-speed isochronous transfer.
6. PIPE1 and PIPE2: Set a value between 1 and 1023 when using full-speed isochronous transfer.
7. PIPE6 and PIPE7: Set a value between 1 and 64.

The high bandwidth transfers used with interrupt transfers and isochronous transfers are not supported.

#### (4) Response PID

The PID bits in DCPCTR and PIPEnCTR are used to set the response PID for each pipe.

The following shows this module operation with various response PID settings:

- Response PID settings when the host controller function is selected:  
The response PID is used to specify the execution of transactions.
  - A. NAK setting: Using pipes is disabled. No transaction is executed.
  - B. BUF setting: Transactions are executed based on the status of the buffer memory.  
For OUT direction: If there are transmit data in the buffer memory, an OUT token is issued.  
For IN direction: If there is an area to receive data in the buffer memory, an IN token is issued.
  - C. STALL setting: Using pipes is disabled. No transaction is executed.

Setup transactions for the DCP are set with the SUREQ bit.

- Response PID settings when the function controller function is selected:  
The response PID is used to specify the response to transactions from the host.
  - A. NAK setting: The NAK response is always returned in response to the generated transaction.
  - B. BUF setting: Responses are made to transactions based on the status of the buffer memory.
  - C. STALL setting: The STALL response is always returned in response to the generated transaction.

For setup transactions, an ACK response is always returned, regardless of the PID setting, and the USB request is stored in the register.

This module may carry out writing to the PID bits, depending on the results of the transaction.

- When the host controller function has been selected and the response PID is set by hardware:
  - A. NAK setting: In the following cases, PID = NAK is set and issuing of tokens is automatically stopped:
    - When a transfer other than isochronous transfer has been performed and no response is returned to the issued token.  
Note: It is recognized as “no response” when no SYNC field is detected within a specified duration.

- When a corrupted packet is received in response to the transmitted token.
  - When a short packet is received in the data stage of a control read transfer.
  - If a short packet is received when the SHTNAK bit in PIPECFG has been set to 1 for bulk transfer.
  - If the transaction counter ended when the SHTNAK bit has been set to 1 for bulk transfer.
- B. BUF setting: There is no BUF writing by this module.
- C. STALL setting: In the following cases, PID = STALL is set and issuing of tokens is automatically stopped:
- When STALL is received in response to the transmitted token.
  - When the size of the receive data packet exceeds the maximum packet size.
- When the function controller function has been selected and the response PID is set by hardware:
    - A. NAK setting: In the following cases, PID = NAK is set and NAK is always returned in response to transactions:
      - When the SETUP token is received normally (DCP only).
      - If the transaction counter ended or a short packet is received when the SHTNAK bit in PIPECFG has been set to 1 for bulk transfer.
    - B. BUF setting: There is no BUF writing by this module.
    - C. STALL setting: In the following cases, PID = STALL is set and STALL is always returned in response to transactions:
      - When the size of the receive data packet exceeds the maximum packet size.
      - When a control transfer sequence error has been detected.

**(5) Registers that Should Not be Set in the USB Communication Enabled (PID = BUF) State**

- The ISEL bit in CFIFOSEL (applies only when DCP is selected)
- The TGL and SCLR bits in CFIFOSIE
- The DCLRM, TRENB, TRCLR, and DEZPM bits in DnFIFOSEL
- The TRNCNT bit in DxFIFOTRN
- Bits in DCPCFG
- Bit in DCPMAXP
- Bits in DCPCTR (excepting the CCPL bit)
- Bits in PIPECFG
- Bits in PIPEBUF

- Bits in PIPEMAXP
- Bits in PIPEPERI
- Bits in PIPEnCTR

## (6) Data PID Sequence Bit

This module automatically toggles the sequence bit in the data PID when data is transferred normally in the control transfer data stage, bulk transfer and interrupt transfer. The sequence bit of the data PID that was transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit switches at the timing at which the ACK handshake is received. When data is received, the sequence bit switches at the timing at which the ACK handshake is transmitted. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

When the function controller function has been selected and control transfer is used, this module automatically sets the sequence bit when a stage transition is made. DATA0 is returned when the setup stage is ended and DATA1 is returned in a status stage. Therefore, software settings are not required. However, when the host controller function has been selected and control transfer is used, the sequence bit should be set by software at the stage transition.

For the Clearfeature request transmission or reception, the data PID sequence bit should be set by software, regardless of whether the host controller function or function controller function is selected.

With pipes for which isochronous transfer has been set, sequence bit operation cannot be carried out using the SQSET bit.

## (7) Response PID = NAK Function

This module has a function that disables pipe operation (PID response = NAK) at the timing at which the final data packet of a transaction is received (this module automatically distinguishes this based on reception of a short packet or the transaction counter) by setting the SHTNAK bit in PIPECFG to 1.

When a double buffer is being used for the buffer memory, using this function enables reception of data packets in transfer units. If pipe operation has disabled, the pipe has to be set to the enabled state again (PID response = BUF) using software.

This function can be used only when bulk transfers are used.

## **(8) Auto Transfer MODE**

With the pipes for bulk transfer (PIPE1 to PIPE5), when the ATREPM bit in PIPEnCTR is set to 1, a transition is made to auto response mode. During an OUT transfer (DIR = 0), OUT-NAK mode is entered, and during an IN transfer (DIR = 1), null auto response mode is entered.

### **(a) OUT-NAK Mode**

With the pipes for bulk OUT transfer, NAK is returned in response to an OUT or PING token and an NRDY interrupt is output when the ATREPM bit is set to 1. To make a transition from normal mode to OUT-NAK mode, OUT-NAK mode should be specified in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). After pipe operation has been enabled, OUT-NAK mode becomes valid. However, if an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To make a transition from OUT-NAK mode to normal mode, OUT-NAK mode should be canceled in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). In normal mode, reception of OUT data is enabled and an ACK is returned in response to a PING token if the buffer is ready to receive data.

### **(b) Null Auto Response Mode**

With the pipes for bulk IN transfer, zero-length packets are continuously transmitted when the ATREPM bit is set to 1.

To make a transition from normal mode to null auto response mode, null auto response mode should be set in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). After pipe operation has been enabled, null auto response mode becomes valid. Before setting null auto response mode, INBUFM = 0 should be confirmed because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, the buffer should be emptied with the ACLRM bit. While a transition to null auto response mode is being made, data should not be written from the FIFO port.

To make a transition from null auto response mode to normal mode, pipe operation disabled state (response PID = NAK) should be retained for the period of zero-length packet transmission (full-speed: 10  $\mu$ s, high-speed: 3  $\mu$ s) before canceling null auto response mode. In normal mode, data can be written from the FIFO port; therefore, packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

### 23.4.4 Buffer Memory

#### (1) Buffer Memory Allocation

Figure 23.9 shows an example of a buffer memory map for this module. The buffer memory is an area shared by the CPU and this module. In the buffer memory status, there are times when the access right to the buffer memory is allocated to the user system (CPU side), and times when it is allocated to this module (SIE side).

The buffer memory sets independent areas for each pipe. In the memory areas, 64 bytes comprise one block, and the memory areas are set using the first block number of the number of blocks (specified using the BUFNMB and BUFSIZE bits in PIPEBUF). Moreover, three FIFO ports are used for access to the buffer memory (reading and writing data). A pipe is assigned to the FIFO port by specifying the pipe number using the CURPIPE bit in C/DnFIFOSEL.

The buffer statuses of the various pipes can be confirmed using the BSTS bit in DCPCTR and the INBUFM bit in PIPEnCTR. Also, the access right of the FIFO port can be confirmed using the FRDY bit in C/DnFIFOCTR.

**Figure 23.9 Example of a Buffer Memory Map**

**(a) Buffer Status**

Tables 23.15 and 23.16 show the buffer status. The buffer memory status can be confirmed using the BSTS bit in DCPCTR and the INBUFM bit in PIPEnCTR. The access direction for the buffer memory can be specified using either the DIR bit in PIPEnCFG or the ISEL bit in CFIFOSEL (when DCP is selected).

The INBUFM bit is valid for PIPE0 to PIPE5 in the sending direction.

For an IN pipe uses double buffer, software can refer the BSTS bit to monitor the buffer memory status of CPU side and the INBUFM bit to monitor the buffer memory status of SIE side. In the case like the BEMP interrupt may not shows the buffer empty status because the CPU (DMAC) writes data slowly, software can use the INBUFM bit to confirm the end of sending.

**Table 23.15 Buffer Status Indicated by the BSTS Bit**

| <b>ISEL or DIR</b>      | <b>BSTS</b> | <b>Buffer Memory State</b>                                                                                                                                                                                            |
|-------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (receiving direction) | 0           | There is no received data, or data is being received.<br>Reading from the CPU is inhibited.                                                                                                                           |
| 0 (receiving direction) | 1           | There is received data, or a zero-length packet has been received.<br>Reading from the CPU is allowed.<br>However, because reading is not possible when a zero-length packet is received, the buffer must be cleared. |
| 1 (sending direction)   | 0           | The transmission has not been finished.<br>Writing to the CPU is inhibited.                                                                                                                                           |
| 1 (sending direction)   | 1           | The transmission has been finished.<br>Writing to the CPU is allowed.                                                                                                                                                 |

**Table 23.16 Buffer Status Indicated by the INBUFM Bit**

| <b>IDIR</b>             | <b>INBUFM</b> | <b>Buffer Memory State</b>                                                   |
|-------------------------|---------------|------------------------------------------------------------------------------|
| 0 (receiving direction) | Invalid       | Invalid                                                                      |
| 1 (sending direction)   | 0             | The transmission has been finished.<br>There is no waiting data to be sent.  |
| 1 (sending direction)   | 1             | There is data to be sent, because CPU (DMAC) has written data to the buffer. |

**(b) Buffer Clearing**

Table 23.17 shows the clearing of the buffer memory by this module. The buffer memory can be cleared using the four bits indicated below.

**Table 23.17 List of Buffer Clearing Methods**

| Bit Name        | BCLR                                     | SCLR                                     | DCLRM                                                                                                         | ACLRM                                                                                   |
|-----------------|------------------------------------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| Register        | CFIFOCTR<br>DnFIFOCTR                    | CFIFOSIE                                 | DnFIFOSEL                                                                                                     | PIPEnCTR                                                                                |
| Function        | Clears the buffer memory on the CPU side | Clears the buffer memory on the SIE side | In this mode, after the data of the specified pipe has been read, the buffer memory is cleared automatically. | This is the auto buffer clear mode, in which all of the received packets are destroyed. |
| Clearing method | Cleared by writing 1                     | Cleared by writing 1                     | 1: Mode valid<br>0: Mode invalid                                                                              | 1: Mode valid<br>0: Mode invalid                                                        |

**(c) Buffer Areas**

Table 23.18 shows the FIFO buffer memory map of this controller. The buffer memory has special fixed areas to which pipes are assigned in advance, and user areas that can be set by the user.

The buffer for the DCP is a special fixed area that is used both for control read transfers and control write transfers.

The PIPE6 and PIPE7 area is assigned in advance, but the area for pipes that are not being used can be assigned to PIPE1 to PIPE5 as a user area.

The settings should ensure that the various pipes do not overlap. Note that each area is twice as large as the setting value in the double buffer.

Also, the buffer size should not be specified using a value that is less than the maximum packet size.

**Table 23.18 Buffer Memory Map**

| Buffer Memory Number | Buffer Size      | Pipe Setting             | Note                                                   |
|----------------------|------------------|--------------------------|--------------------------------------------------------|
| H'0 to H'3           | 256 bytes        | DCP special fixed area   | Single buffer, continuous transfers enabled            |
| H'4                  | 64 bytes         | Fixed area for PIPE6     | Single buffer                                          |
| H'5                  | 64 bytes         | Fixed area for PIPE7     | Single buffer                                          |
| H'6 to H'7F          | Up to 7808 bytes | PIPE1 to PIPE5 user area | Double buffer can be set, continuous transfers enabled |

**(d) Auto Buffer Clear Mode Function**

With this module, all of the received data packets are discarded if the ACLRM bit in PIPEnCTR is set to 1. If a normal data packet has been received, the ACK response is returned to the host controller. This function can be set only in the buffer memory reading direction.

Also, if the ACLRM bit is set to 1 and then to 0, the buffer memory of the pipe can be cleared regardless of the access direction.

An access cycle of at least 100 ns is required between ACLRM = 1 and ACLRM = 0.

**(e) Buffer Memory Specifications (Single/Double Setting)**

Either a single or double buffer can be selected for PIPE1 to PIPE5, using the DBLB bit in PIPEnCFG. The double buffer is a function that assigns two memory areas specified with the BUFSIZE bit in PIPEBUF to the same pipe. Figure 23.10 shows an example of buffer memory settings for this module.

**Figure 23.10 Example of Buffer Memory Settings**

### (f) Buffer Memory Operation (Continuous Transfer Setting)

Either the continuous transfer mode or the non-continuous transfer mode can be selected, using the CNTMD bit in DCPCFG and PIPEnCFG. This selection is valid for PIPE0 to PIPE5.

The continuous transfer mode function is a function that sends and receives multiple transactions in succession. When the continuous transfer mode is set, data can be transferred without interrupts being issued to the CPU, up to the buffer sizes assigned for each of the pipes.

In the continuous sending mode, the data being written is divided into packets of the maximum packet size and sent. If the data being sent is less than the buffer size (short packet, or the integer multiple of the maximum packet size is less than the buffer size), BVAL = 1 must be set after the data being sent has been written.

In the continuous reception mode, interrupts are not issued during reception of packets up to the buffer size, until the transaction counter has ended, or a short packet is received.

Figure 23.11 shows an example of buffer memory operation for this module.

**Figure 23.11 Example of Buffer Memory Operation**

## (2) FIFO Port Functions

Table 23.19 shows the settings for the FIFO port functions of this module. In write access, writing data until the buffer is full (or the maximum packet size for non-continuous transfers) automatically enables sending of the data. To enable sending of data before the buffer is full (or before the maximum packet size for non-continuous transfers), the BVAL bit in C/DnFIFOCTR must be set to end the writing. Also, to send a zero-length packet, the BCLR bit in the same register must be used to clear the buffer and then the BVAL bit set in order to end the writing.

In read access, reception of new packets is automatically enabled if all of the data has been read. Data cannot be read when a zero-length packet is being received (DTLN = 0), so the BCLR bit in the register must be used to release the buffer. The length of the data being received can be confirmed using the DTLN bit in C/DnFIFOCTR.

**Table 23.19 FIFO Port Function Settings**

| Register Name         | Bit Name | Function                                                                             | Note            |
|-----------------------|----------|--------------------------------------------------------------------------------------|-----------------|
| C/DnFIFOSEL           | REW      | Buffer memory rewind (re-read, rewrite)                                              |                 |
|                       | DCLRM    | Automatically clears data received for a specified pipe after the data has been read | For DnFIFO only |
|                       | DREQE    | Asserts DREQ signal                                                                  | For DnFIFO only |
|                       | MBW      | FIFO port access bit width                                                           |                 |
|                       | TRENB    | Enables transaction counter operation                                                | For DnFIFO only |
|                       | TRCLR    | Clears the current number of transactions                                            | For DnFIFO only |
|                       | DEZPM    | zero-length packet addition mode                                                     | For DMA only    |
|                       | ISEL     | FIFO port access direction                                                           | For DCP only    |
| C/DnFIFOCTR           | BVAL     | Ends writing to the buffer memory                                                    |                 |
|                       | BCLR*    | Clears the buffer memory on the CPU side                                             |                 |
|                       | DTLN     | Confirms the length of received data                                                 |                 |
| DnFIFOTRN             | TRNCNT   | Sets the received transaction count                                                  | For DnFIFO only |
| CFIFOSIE (except DCP) | TGL      | CPU/SIE buffer toggle                                                                | For CFIFO only  |
|                       | SCLR     | Clears the buffer memory on the SIE side                                             | For CFIFO only  |

Note: \* When CFIFOSEL.CURPIPE = DCP, setting CFIFOCTR.BCLR to 1 also clears the buffer memory on the SIE side.

**(a) FIFO Port Selection**

Table 23.20 shows the pipes that can be selected with the various FIFO ports. The pipe to be accessed is selected using the CURPIPE bit in C/DnFIFOSEL. After the pipe has been selected,  $FRDY = 1$  should be confirmed before accessing the FIFO port.

Also, the bus width to be accessed should be selected using the MBW bit. The buffer memory access direction conforms to the DIR bit in PIPEnCFG. The ISEL bit determines this only for the DCP.

**Table 23.20 FIFO Port Access Categorized by Pipe**

| Pipe           | Access Method | Port that can be Used       |
|----------------|---------------|-----------------------------|
| DCP            | CPU access    | CFIFO port register         |
| PIPE1 to PIPE7 | CPU access    | CFIFO port register         |
|                | DMA access    | D0FIFO/D1FIFO port register |

**(b) REW Bit**

It is possible to temporarily stop access to the pipe currently being accessed, access a different pipe, and then continue processing using the current pipe once again. The REW bit in C/DnFIFOSEL is used for this.

If a pipe is selected when the REW bit is set to 1 and at the same time the CURPIPE bit in C/DnFIFOSEL is set, the pointer used for reading from and writing to the buffer memory is reset, and reading or writing can be carried out from the first byte. Also, if a pipe is selected with 0 set for the REW bit, data can be read and written in continuation of the previous selection, without the pointer used for reading from and writing to the buffer memory being reset.

To access the FIFO port,  $FRDY = 1$  must be confirmed after selecting a pipe.

**(c) Reading the Buffer Memory on the SIE (CFIFO Port Reading Direction)**

Even in the  $FRDY = 0$  state, when data cannot be read from the buffer memory, confirming the SBUSY bit in CFIFOSIE and setting 1 for the TGL bit makes it possible for this module to read and access data on the SIE side. PID = NAK should be set and SBUSY = 0 confirmed, and then TGL = 1 written. This module is then able to read data from CFIFO. This function can be used only in the buffer memory reading direction. Also, the BRDY interrupt is generated by operation of the TGL bit.

1 should not be written for the TGL bit in the following circumstances.

- When DCP is selected
- While the buffer memory is being read
- Pipes in the buffer memory writing direction

#### **(d) Clearing the Buffer Memory on the SIE (CFIFO Port Writing Direction)**

This module can cancel data that is waiting to be sent, by confirming the SBUSY bit in CFIFOSIE and setting 1 for the SCLR bit.

PID = NAK should be set and SBUSY = 0 confirmed, and then SCLR = 1 written. This module is then able to write new data from CFIFO. This function can be used only in the buffer memory writing direction. Also, the BRDY interrupt is generated by the SCLR bit.

1 should not be written for the SCLR bit in the following circumstances.

- When DCP is selected
- While data is being written to the buffer memory
- Pipes in the buffer memory reading direction

#### **(e) Transaction Counter (D0FIFO/D1FIFO Port Reading Direction)**

When the specified number of transactions has been completed in the data packet receiving direction, this module is able to recognize that the transfer has ended. The transaction counter is a function that operates when the pipe selected by means of the D0FIFO/D1FIFO port has been set in the direction of reading data from the buffer memory. The transaction counter has TRNCNT that specifies the number of transactions and a current counter that counts the transactions internally. When the current counter matches the number of transactions specified in TRNCNT, reading is enabled for the buffer memory. The current counter of the transaction counter function is initialized by the TRCLR bit, so that the transactions can be counted again starting from the beginning. The information read by TRNCNT differs depending on the setting of the TRENb bit.

- TRENb = 0: The set transaction counter value can be read.
- TRENb = 1: The value of the current counter that counts the transactions internally can be read.

The conditions for changing the CURPIPE bit are as noted below.

- The CURPIPE bit should not be changed until the transaction for the specified pipe has ended.
- The CURPIPE bit cannot be changed if the current counter has not been cleared.

The operation conditions for the TRCLR bit are as noted below.

- If the transactions are being counted and PID = BUF, the current counter cannot be cleared.
- If there is any data left in the buffer, the current counter cannot be cleared.

#### **(f) FIFO Port Access Wait Specification**

Access to FIFO ports in this module has the following restrictions.

- Do not exceed a transfer speed of 48 MB/s.

This module can limit access cycle through the access wait set (FWAIT) bit so that the peripheral clock frequency is not limited.

The FWAIT bit can be set to each FIFO port, and can be efficiently set according to the CPU speed, the transfer source access cycle, and so on.

- Conditions  
Access direction: writing to FIFO  
Peripheral clock frequency: 66 MHz  
MBW bit setting value: 10 (32-bit width)  
Access type: After transfer data is read from the on-chip memory (the source), it is written to the FIFO port. In this case, 2 clock cycles are required for source access.
- Example of calculation  
$$(2 + (\text{FWAIT} + 2)) \times 1/66 \text{ MHz} \geq 1/48 \text{ MHz} \times 4 (32 \text{ bits})$$
$$\text{FWAIT} = 2 (4 \text{ clock cycles})$$

#### **(g) Methods of Accessing FIFO Port for Fractional-Width Data**

If a unit of data narrower than the bit width specified by the MBW bits in the FIFO port select register is to be read from a FIFO port, read the data with the bit width specified by the MBW bits and then use software to discard the unnecessary data.

If a unit of data narrower than the bit width specified by the MBW bits in the FIFO port select register is to be written to a FIFO port, access the FIFO port as shown in the example below. The example shows how to write 24-bit-wide data when the FIFO port width has been specified as 32 bits (MBW = 10).

- Example 1 of writing fractional-width data: one 16-bit write operation followed by an 8-bit write operation.

**Figure 23.12 Example 1 of Writing Fractional-Width Data to the FIFO Port**

- Example 2 of writing fractional-width data: three 8-bit write operations.

**Figure 23.13 Example 2 of Writing Fractional-Width Data to the FIFO Port**

### (h) Method of Changing Setting of MBW Bits when Selected CURPIPE Is Set to Buffer Memory Read Direction

Write to the MBW bits in the FIFO port select registers (CFIFOSEL, D0FIFOSEL, and D1FIFOSEL) and set the CURPIPE bits simultaneously. When the DCP setting (CURPIPE = 000) is selected in the CFIFO register, set the CURPIPE bits or ISEL bit and write to the MBW bits simultaneously.

Follow the procedure below to change the setting of only the MBW bits for the currently selected pipe. However, once a buffer memory read operation has started, do not change the setting of the MBW bits until all the data has been read.

It is possible to change the setting of only the MBW bits directly when the selected CURPIPE is set to the buffer memory write direction. However, once a buffer memory write operation has started, do not change the bit width from 8 bits to 16 or 32 bits, or from 16 bits to 32 bits.

- When CURPIPE of DFIFO0, DFIFO1, or CFIFO is set to other than DCP (000)

**Figure 23.14 Example of Changing the MBW Setting when CURPIPE of DFIFO0, DFIFO1, or CFIFO Is Set to Other Than DCP (000)**

### (3) DMA Transfers (D0FIFO/D1FIFO port)

#### (a) Overview of DMA Transfers

For pipes 1 to 7, the FIFO port can be accessed using the DMAC. When accessing the buffer for the pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.

The unit of transfer to the FIFO port should be selected using the MBW bit in DnFIFOSEL and the pipe targeted for the DMA transfer should be selected using the CURPIPE bit. The selected pipe should not be changed during the DMA transfer.

#### (b) Auto Recognition of DMA Transfer Completion

With this module, it is possible to complete FIFO data writing through DMA transfer by controlling DMA transfer end signal input. A DMA transfer signal is output from the DMAC when the number of DMA transfers specified in the DMA transfer count register (DMATCR) has been performed. When a DMA transfer end signal is sampled, the module enables buffer memory transmission (the same condition as when BVAL = 1). The TENDE bit in DnFBCFG can be used to specify whether a DMA transfer end signal is sampled or not.

#### (c) Zero-Length Packet Addition Mode (D0FIFO/D1FIFO Port Writing Direction)

With this module, it is possible to add and send one zero-length packet after all of the data has been sent, under the condition below, by setting 1 to the DEZPM bit in DnFIFOSEL. This function can be set only if the buffer memory writing direction has been set (a pipe in the sending direction has been set for the CURPIPE bits).

- If the number of data bytes written to the buffer memory is a multiple of the integer for the maximum packet size when a DMA transfer end signal is sampled.

#### (d) DnFIFO Auto Clear Mode (D0FIFO/D1FIFO Port Reading Direction)

If 1 is set for the DCLRM bit in DnFIFOSEL, the module automatically clears the buffer memory of the corresponding pipe when reading of the data from the buffer memory has been completed.

Table 23.21 shows the packet reception and buffer memory clearing processing for each of the various settings. As shown, the buffer clear conditions depend on the value set to the BFRE bit. Using the DCLRM bit eliminates the need for the buffer to be cleared by software even if a situation occurs that necessitates clearing of the buffer. This makes it possible to carry out DMA transfers without involving software.

This function can be set only in the buffer memory reading direction.

**Table 23.21 Packet Reception and Buffer Memory Clearing Processing**

| <div style="text-align: center;"> <div>Register Setting</div> <div>Buffer Status<br/>When Packet is Received</div> </div> | DCLRM = 0                  |                            | DCLRM = 1                  |                            |
|---------------------------------------------------------------------------------------------------------------------------|----------------------------|----------------------------|----------------------------|----------------------------|
|                                                                                                                           | BFRE = 0                   | BFRE = 1                   | BFRE = 0                   | BFRE = 1                   |
| Buffer full                                                                                                               | Doesn't need to be cleared | Doesn't need to be cleared | Doesn't need to be cleared | Doesn't need to be cleared |

**(e) BRDY Interrupt Timing Selection Function**

By setting the BFRE bit setting in PIPECFG, it is possible to keep the BRDY interrupt from being generated when a data packet consisting of the maximum packet size is received.

When using DMA transfers, this function can be used to generate an interrupt only when the last data item has been received. The last data item refers to the reception of a short packet, or the ending of the transaction counter. When the BFRE bit is set to 1, the BRDY interrupt is generated after the received data has been read. When the DTLN bit in DnFIFOCTR is read, the length of the data received in the last data packet to have been received can be confirmed.

Table 23.22 shows the timing at which the BRDY interrupts are generated by this module.

**Table 23.22 Timing at which BRDY Interrupts are Generated**

| Register setting<br>Buffer State<br>When Packet is Received | BFRE = 0                | BFRE = 1                                                                    |
|-------------------------------------------------------------|-------------------------|-----------------------------------------------------------------------------|
| Buffer full (normal packet received)                        | When packet is received | Not generated                                                               |
| Zero-length packet received                                 | When packet is received | When packet is received                                                     |
| Normal short packet received                                | When packet is received | When reading of the received data from the buffer memory has been completed |
| Transaction count ended                                     | When packet is received | When reading of the received data from the buffer memory has been completed |

Note: This function is valid only in the reading direction of reading from the buffer memory. In the writing direction, the BFRE bit should be fixed at 0.

#### (4) Timing at which the FIFO Port can be Accessed

##### (a) Timing at which the FIFO Port can be Accessed when Switching Pipes

Figure 23.15 shows a diagram of the timing up to the point where the FRDY and DTLN bits are determined when the pipe specified by the FIFO port has been switched (the CURPIPE bit in C/DnFIFOSEL has been changed).

If the CURPIPE bits have been changed, access to the FIFO port should be carried out after waiting 450 ns and 8 clock cycles at a peripheral clock after writing to C/DnFIFOSEL.

The same timing applies with respect to the CFIFO port, when the ISEL bit is changed.

**Figure 23.15 Timing at which the FRDY and DTLN Bits are Determined after Changing a Pipe**

**(b) Timing at which the FIFO Port can be Accessed after Reading/Writing has been Completed when Using a Double Buffer**

Figure 23.16 shows the timing at which, when using a pipe with a double buffer, the other buffer can be accessed after reading from or writing to one buffer has been completed.

When using a double buffer, access to the FIFO port should be carried out after waiting 300 ns and 6 clock cycles at a peripheral clock after the access made just prior to toggling.

The same timing applies when a short packet is being sent based on the BVAL = 1 setting using the IN direction pipe.

**Figure 23.16 Timing at which the FRDY and DTLN Bits are Determined after Reading from or Writing to a Double Buffer has been Completed**

### 23.4.5 Control Transfers (DCP)

Data transfers of the data stage of control transfers are done using the default control pipe (DCP). The DCP buffer memory is a 256-byte single buffer, and is a fixed area that is shared for both control reading and control writing. The buffer memory can be accessed through the CFIFO port.

#### (1) Control Transfers when the Host Controller Function is Selected

##### (a) Setup Stage

USQREQ, USBVAL, USBINDX, and USBLENG are the registers that are used to transmit a USB request for setup transactions. Writing setup packet data to the registers and writing 1 to the SUREQ bit in DCPCTR transmits the specified data for setup transactions. Upon completion of transactions, the SUREQ bit is cleared to 0. The above USB request registers should not be modified while SUREQ = 1. The device address for setup transactions is specified using the DEVSEL bits in DCPMAXP.

When the data for setup transactions has been sent, a SIGN or SACK interrupt request is generated according to the response received from the peripheral side (SIGN1 or SACK bits in INTSTS1), by means of which the result of the setup transactions can be confirmed.

A data packet of DATA0 (USB request) is transmitted as the data packet for the setup transactions regardless of the setting of the SQMON bit in DCPCTR.

##### (b) Data Stage

Data transfers are done using the DCP buffer memory.

The access direction of the DCP buffer memory should be specified using the ISEL bit in CFIFOSEL.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Transaction is done by setting the data PID = DATA1 and the PID bit = BUF using the SQSET bit in DCPCFG. Completion of data transfer is detected using the BRDY or BEMP interrupts.

Setting continuous transfer mode allows data transfers over multiple packets. Note that when continuous transfer mode is set for the receiving direction, the BRDY interrupt is not generated until the buffer becomes full or a short packet is received (the integer multiple of the maximum packet size, and less than 256 bytes).

For control write transfers, when the number of data bytes to be sent is the integer multiple of the maximum packet size, software must control so as to send a zero-length packet at the end.

For data transfers in the sending direction during high-speed operation, the PING packet is sent. Control for the PING packet is done in the same manner as bulk transfers.

### (c) Status Stage

Zero-length packet data transfers are done in the direction opposite to that in the data stage. As with the data stage, data transfers are done using the DCP buffer memory. Transactions are done in the same manner as the data stage.

For the data packets of the status stage, the data PID must be transferred as DATA1. The data PID should be set to DATA1 using the SQSET bit in DCPCFG.

For reception of a zero-length packet, the received data length must be confirmed using the DTLN bits in CFIFOCTR after the BRDY interrupt is generated, and the buffer memory must then be cleared using the BCLR bit in C/DnFIFOCTR.

For data transfers in the sending direction during high-speed operation, the PING packet is sent. Control for the PING packet is done in the same manner as the bulk transfers.

## (2) Control Transfers when the Function Controller Function is Selected

### (a) Setup Stage

This module always sends an ACK response in response to a setup packet that is normal with respect to this module. The operation of this module operates in the setup stage is noted below.

1. When a new USB request is received, this module sets the following registers:
  - Set the VALID bit in INTSTS0 to 1.
  - Set the PID bit in DCPCTR to NAK.
  - Set the CCPL bit in DCPCTR to 0.
2. When a data packet is received right after the SETUP packet, the USB request parameters are stored in USBREQ, USBVAL, USBINDX, and USBLENG.

Response processing with respect to the control transfer should always be carried out after first setting VALID = 0. In the VALID = 1 state, PID = BUF cannot be set, and the data stage cannot be terminated.

Using the function of the VALID bit, this module is able to interrupt the processing of a request currently being processed if a new USB request is received during a control transfer, and can send a response in response to the newest request.

Also, this module automatically judges the direction bit (bit 8 of the `bmRequestType`) and the request data length (`wLength`) of the USB request that was received, and then distinguishes between control read transfers, control write transfers, and no-data control transfers, and controls the stage transition. For a wrong sequence, the sequence error of the control transfer stage transition interrupt is generated, and the software is notified. For information on the stage control of this module, see figure 23.18.

### **(b) Data Stage**

Data transfers corresponding to USB requests that have been received should be done using the DCP. Before accessing the DCP buffer memory, the access direction should be specified using the ISEL bit in `CFIFOSEL`.

A transaction is executed by setting the PID bits in the `DCPCTR` register to `BUF`. The `BRDY` interrupt or the `BEMP` interrupt can be used to detect the end of data transfer. Use the `BRDY` interrupt to detect the end of control write transfers and the `BEMP` interrupt to detect the end of control read transfers.

With control write transfers during high-speed operation, the `NYET` handshake response is carried out based on the state of the buffer memory. For information on the `NYET` handshake, see section 23.4.6 (2), `NYET` Handshake Control when the Function Controller Function is Selected.

### **(c) Status Stage**

Control transfers are terminated by setting the `CCPL` bit to 1 with the PID bit in `DCPCTR` set to `PID = BUF`.

After the above settings have been entered, this module automatically executes the status stage in accordance with the data transfer direction determined at the setup stage. The specific procedure is as follows.

1. For control read transfers:

The zero-length packet is received from the USB host, and this module sends an `ACK` response.

2. For control write transfers and no-data control transfers:

This module sends a zero-length packet and receives an `ACK` response from the USB host.

### (d) Control Transfer Auto Response Function

This module automatically responds to a normal SET\_ADDRESS request. If any of the following errors occur in the SET\_ADDRESS request, a response from the software is necessary.

1. bmRequestType  $\neq$  H'00
2. wIndex  $\neq$  H'00
3. wLength  $\neq$  H'00
4. wValue  $>$  H'7F
5. DVSQ = 011 (Configured)

For all requests other than the SET\_ADDRESS request, a response is required from the corresponding software.

### 23.4.6 Bulk Transfers (PIPE1 to PIPE5)

The buffer memory specifications for bulk transfers (single/double buffer setting, or continuous/non-continuous transfer mode setting) can be selected. The maximum size that can be set for the buffer memory is 2 kbytes. The buffer memory state is controlled by this module, with a response sent automatically for a PING packet/NYET handshake. If MXPS = 0 has been set, the interrupt specifications are different from those of the other pipes. For details, see section 23.4.3 (3), Maximum Packet Size Setting.

#### (1) PING Packet Control when the Host Controller Function is Selected

This module automatically sends a PING packet in the OUT direction.

On receiving an ACK handshake in the initial state in which PING packet sending mode is set, this module sends an OUT packet as noted below. Reception of an NAK or NYET handshake returns this module to PING packet sending mode. This control also applies to the control transfers in the data stage and status stage.

1. Sets OUT data sending mode.
2. Sends a PING packet.
3. Receives an ACK handshake.
4. Sends an OUT data packet.
5. Receives an ACK handshake.  
(Repeats steps 4 and 5.)
6. Sends an OUT data packet.
7. Receives an NAK/NYET handshake.

8. Sends a PING packet.

This controller is returned to PING packet sending mode by a power-on reset, a software reset, receiving a NYET/NAK handshake, setting or clearing the sequence toggle bits (SQSET and SQCLR), and setting the buffer clear bit (ACLRM) in PIPEnCTR.

## (2) NYET Handshake Control when the Function Controller Function is Selected

Table 23.23 shows the NYET handshake responses of this module. The NYET response of this module is made in conformance with the conditions noted below. When a short packet is received, however, the response will be an ACK response instead of a NYET packet response. The same applies to the data stages of control write transfers.

**Table 23.23 NYET Handshake Responses**

| Value Set<br>for PID Bit in<br>DCPCTR | Buffer<br>Memory<br>State | Token           | Response    | Note                                                    |
|---------------------------------------|---------------------------|-----------------|-------------|---------------------------------------------------------|
| NAK/STALL                             | —                         | SETUP           | ACK         | —                                                       |
|                                       | —                         | IN/OUT/<br>PING | NAK/STALL   | —                                                       |
| BUF                                   | —                         | SETUP           | ACK         | —                                                       |
|                                       | RCV-BRDY1                 | OUT/PING        | ACK         | If an OUT token is received, a data packet is received. |
|                                       | RCV-BRDY2                 | OUT             | NYET        | Notifies whether a data packet can be received          |
|                                       | RCV-BRDY2                 | OUT (Short)     | ACK         | Notifies whether a data packet can be received          |
|                                       | RCV-BRDY2                 | PING            | ACK         | Notifies that a data packet can be received             |
|                                       | RCV-NRDY                  | OUT/PING        | NAK         | Notifies that a data packet cannot be received          |
|                                       | TRN-BRDY                  | IN              | DATA0/DATA1 | A data packet is transmitted                            |
|                                       | TRN-BRDY                  | IN              | NAK         | TRN-NRDY                                                |

### [Legend]

RCV-BRDY1: When an OUT/PING token is received, there is space in the buffer memory for two or more packets.

RCV-BRDY2: When an OUT token is received, there is only enough space in the buffer memory for one packet.

RCV-NRDY: When a PING token is received, there is no space in the buffer memory.

TRN-BRDY: When an IN token is received, there is data to be sent in the buffer memory.

TRN-NRDY: When an IN token is received, there is no data to be sent in the buffer memory.

### 23.4.7 Interrupt Transfers (PIPE6 and PIPE7)

This module carries out interrupt transfers in accordance with the timing controlled by the host controller. For interrupt transfers, PING packets are ignored (no responses are sent), and the ACK, NAK, and STALL responses are carried out without an NYET handshake response being made. This module does not support high bandwidth transfers of interrupt transfers.

#### (1) Interval Counter during Interrupt Transfers when the Host Controller Function is Selected

For interrupt transfers, intervals between transactions are set in the IITV bits in PIPEPERI. This controller issues an interrupt transfer token based on the specified intervals.

##### (a) Counter Initialization

This controller initializes the interval counter under the following conditions.

- Power-on reset:  
The IITV bits are initialized.
- Software reset:  
The IITV bits are initialized.
- Buffer memory initialization using the ACLRM bit:  
The IITV bits are not initialized but the count value is. Setting the ACLRM bit to 0 starts counting from the value set in the IITV bits.

Note that the interval counter is not initialized in the following case.

- USB bus reset, USB suspended:  
The IITV bits are not initialized. Setting 1 to the UACT bit starts counting from the value before entering the USB bus reset state or USB suspended state.

##### (b) Operation when Transmission/Reception is Impossible at Token Issuance Timing

This module cannot issue tokens even at token issuance timing in the following cases. In such a case, this module attempts transactions at the subsequent interval.

- When the PID is set to NAK or STALL.
- When the buffer memory is full at the token sending timing in the receiving (IN) direction.
- When there is no data to be sent in the buffer memory at the token sending timing in the sending (OUT) direction.

### 23.4.8 Isochronous Transfers (PIPE1 and PIPE2)

This module has the following functions pertaining to isochronous transfers.

1. Notification of isochronous transfer error information
2. Interval counter (specified by the IITV bit)
3. Isochronous IN transfer data setup control (IDLY function)
4. Isochronous IN transfer buffer flush function (specified by the IFIS bit)

This module does not support the High Bandwidth transfers of isochronous transfers.

Note: When using isochronous OUT transfer, see section 23.5.1, Note on Using Isochronous OUT Transfer.

#### (1) Error Detection with Isochronous Transfers

This module has a function for detecting the error information noted below, so that when errors occur in isochronous transfers, software can control them. Tables 23.24 and 23.25 show the priority in which errors are confirmed and the interrupts that are generated.

1. PID errors
  - If the PID of the packet being received is illegal
2. CRC errors and bit stuffing errors
  - If an error occurs in the CRC of the packet being received, or the bit stuffing is illegal
3. Maximum packet size exceeded
  - The maximum packet size exceeded the set value.
4. Overrun and underrun errors
  - When host controller function is selected:
    - When using isochronous IN transfers (reception), the IN token was received but the buffer memory is not empty.
    - When using isochronous OUT transfers (transmission), the OUT token was transmitted, but the data was not in the buffer memory.
  - When function controller function is selected:
    - When using isochronous IN transfers (transmission), the IN token was received but the data was not in the buffer memory.
    - When using isochronous OUT transfers (reception), the OUT token was received, but the buffer memory was not empty.

## 5. Interval errors

- During an isochronous IN transfer, the token could not be received during the interval frame.
- During an isochronous OUT transfer, the OUT token was received during frames other than the interval frame.

**Table 23.24 Error Detection when a Token is Received**

| <b>Detection Priority</b> | <b>Error</b>                      | <b>Generated Interrupt and Status</b>                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                         | PID errors                        | No interrupts are generated in both cases when the host controller function is selected and the function controller function is selected (ignored as a corrupted packet).                                                                                                                                                                                                                                                               |
| 2                         | CRC error and bit stuffing errors | No interrupts generated in both cases when the host controller function is selected and the function controller function is selected (ignored as a corrupted packet).                                                                                                                                                                                                                                                                   |
| 3                         | Overrun and underrun errors       | <p>An NRDY interrupt is generated to set the OVRN bit in both cases when host controller function is selected and function controller function is selected.</p> <p>When the host controller function is selected, no tokens are transmitted.</p> <p>When the function controller function is selected, a zero-length packet is transmitted in response to IN token. However, no data packets are received in response to OUT token.</p> |
| 4                         | Interval errors                   | An NRDY interrupt is generated when the function controller function is selected. It is not generated when the host controller function is selected.                                                                                                                                                                                                                                                                                    |

**Table 23.25 Error Detection when a Data Packet is Received**

| <b>Detection<br/>Priority Order</b> | <b>Error</b>                       | <b>Generated Interrupt and Status</b>                                                                                                                                    |
|-------------------------------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                                   | PID errors                         | No interrupts are generated (ignored as a corrupted packet)                                                                                                              |
| 2                                   | CRC error and bit stuffing errors  | An NRDY interrupt is generated to set the CRCE bit in both cases when the host controller function is selected and the function controller function is selected.         |
| 3                                   | Maximum packet size exceeded error | A BEMP interrupt is generated to set the PID bits to STALL in both cases when the host controller function is selected and the function controller function is selected. |

**(2) DATA-PID**

Because High Bandwidth transfers are not supported, the DATA-PID added with the USB 2.0 standard is supported as shown below.

1. IN direction
  - DATA0: Sent as data packet PID
  - DATA1: Not sent
  - DATA2: Not sent
  - mData: Not sent
2. OUT direction (when using full-speed operation)
  - DATA0: Received normally as data packet PID
  - DATA1: Received normally as data packet PID
  - DATA2: Packets are ignored
  - mData: Packets are ignored
3. OUT direction (when using high-speed operation)
  - DATA0: Received normally as data packet PID
  - DATA1: Received normally as data packet PID
  - DATA2: Received normally as data packet PID
  - mData: Received normally as data packet PID

### (3) Interval Counter

The isochronous interval can be set using the IITV bits in PIPEPERI. The interval counter enables the functions shown in table 23.26 when the function controller function is selected. When the host controller function is selected, this module generates the token issuance timing. When the host controller function is selected, the interval counter operation is the same as the interrupt transfer operation.

**Table 23.26 Functions of the Interval Counter when the Function Controller Function is Selected**

| Transfer Direction | Function                                 | Conditions for Detection                                                                          |
|--------------------|------------------------------------------|---------------------------------------------------------------------------------------------------|
| IN                 | IN buffer flush function                 | When a token cannot be normally received in the interval frame during an isochronous IN transfer  |
| OUT                | Notifies that a token not being received | When a token cannot be normally received in the interval frame during an isochronous OUT transfer |

The interval count is carried out when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is damaged. The frame interval that can be set is the  $2^{\text{IITV}}$  frame or  $2^{\text{IITV}} \mu$  frames.

#### (a) Counter Initialization when the Function Controller Function is Selected

This module initializes the interval counter under the following conditions.

1. Power-on reset  
The IITV bit is initialized.
2. Software reset  
The IITV bit is initialized.
3. USB bus reset  
The IITV bit is not initialized, but the counting is initialized.
4. Buffer memory initialization using the ACLRM bit  
The IITV bits are not initialized but the count value is. Setting the ACLRM bit to 0 starts counting from the value set in the IITV bits.

After the interval counter has been initialized, the counter is started under the following conditions 1 or 2 when a packet has been transferred normally.

1. An SOF is received following transmission of data in response to an IN token, in the PID = BUF state.
2. An SOF is received after data following an OUT token is received in the PID = BUF state.

The interval counter is not initialized under the conditions noted below.

1. When the PID bit is set to NAK or STALL

The interval timer does not stop. This module attempts the transactions at the subsequent interval.

2. The USB is suspended

The IITV bit is not initialized. When the SOF has been received, the counter is restarted from the value prior to the reception of the SOF.

#### **(4) Setup of Data to be Transmitted using Isochronous Transfer when the Function Controller Function is Selected**

With isochronous data transmission using this module in function controller function, after data has been written to the buffer memory, a data packet can be sent with the next frame in which an SOF packet is detected. This function is called the isochronous transfer transmission data setup function, and it makes it possible to designate the frame from which transmission began.

If a double buffer is used for the buffer memory, transmission will be enabled for only one of the two buffers even after the writing of data to both buffers has been completed, that buffer memory being the one to which the data writing was completed first. For this reason, even if multiple IN tokens are received, the only buffer memory that can be sent is one packet's worth of data.

When an IN token is received, if the buffer memory is in the transmission enabled state, this module transmits the data. If the buffer memory is not in the transmission enabled state, however, a zero-length packet is sent and an underrun error occurs.

Figure 23.17 shows an example of transmission using the isochronous transfer transmission data setup function with this module, when IITV = 0 (every frame) has been set.

**Figure 23.17 Example of Data Setup Function Operation**

### (5) Isochronous Transfer Transmission Buffer Flush when the Function Controller Function Is Selected

If an SOF packet or a  $\mu$ SOF packet is received without receiving an IN token in the interval frame during isochronous data transmission, this module operates as if an IN token had been corrupted, and clears the buffer for which transmission is enabled, putting that buffer in the writing enabled state.

If a double buffer is being used and writing to both buffers has been completed, the buffer memory that was cleared is seen as the data having been sent at the same interval frame, and transmission is enabled for the buffer memory that is not discarded with SOF or  $\mu$ SOF packets reception.

The timing at which the operation of the buffer flush function varies depending on the value set for the IITV bit.

1. If IITV = 0

The buffer flush operation starts from the next frame after the pipe becomes valid.

2. In any cases other than IITV = 0

The buffer flush operation is carried out subsequent to the first normal transaction.

Figure 23.18 shows an example of the buffer flush function of this module. When an unanticipated token is received prior to the interval frame, this module sends the written data or a zero-length packet according to the buffer state.

**Figure 23.18 Example of Buffer Flush Function Operation**

Figure 23.19 shows an example of this module generating an interval error. There are five types of interval errors, as shown below. The interval error is generated at the timing indicated by (1) in the figure, and the IN buffer flush function is activated.

If an interval error occurs during an IN transfers, the buffer flush function is activated; and if it occurs during an OUT transfer, an NRDY interrupt is generated.

The OVRN bit should be used to distinguish between NRDY interrupts such as received packet errors and overrun errors.

In response to tokens that are shaded in the figure, responses occur based on the buffer memory status.

1. IN direction:

- If the buffer is in the transmission enabled state, the data is transferred as a normal response.
- If the buffer is in the transmission disabled state, a zero-length packet is sent and an underrun error occurs.

2. OUT direction:

- If the buffer is in the reception enabled state, the data is received as a normal response.

— If the buffer is in the reception disabled state, the data is discarded and an overrun error occurs.

**Figure 23.19 Example of an Interval Error Being Generated when IITV = 1**

### 23.4.9 SOF Interpolation Function

When the function controller function is selected and if data could not be received at intervals of 1 ms (when using full-speed operation) or 125  $\mu$ s (when using high-speed operation) because an SOF packet was corrupted or missing, this module interpolates the SOF. The SOF interpolation operation begins when USBE = 1, SCKE = 1 and an SOF packet is received. The interpolation function is initialized under the following conditions.

- Power-on reset
- Software reset
- USB bus reset
- Suspended state detected

Also, the SOF interpolation operates under the following specifications.

- 125  $\mu$ s/1 ms conforms to the results of the reset handshake protocol.
- The interpolation function is not activated until an SOF packet is received.
- After the first SOF packet is received, either 125  $\mu$ s or 1 ms is counted with the USB clock of 48 MHz, and interpolation is carried out.
- After the second and subsequent SOF packets are received, interpolation is carried out at the previous reception interval.

- Interpolation is not carried out in the suspended state or while a USB bus reset is being received. (With suspended transitions in high-speed operation, interpolation continues for 3 ms after the last packet is received.)

This module supports the following functions based on the SOF detection. These functions also operate normally with SOF interpolation, if the SOF packet was corrupted.

- Refreshing of the frame number and the micro-frame number
- SOFR interrupt and  $\mu$ SOF lock
- Isochronous transfer interval count

If an SOF packet is missing when full-speed operation is being used, the FRNM bit in FRMNUM0 is not refreshed.

If a  $\mu$ SOF packet is missing during high-speed operation, the UFRNM bit in FRMNUM1 is refreshed.

However, if a  $\mu$ SOF packet for which the  $\mu$ FRNM = 000 is missing, the FRNM bit is not refreshed. In this case, the FRNM bit is not refreshed even if successive  $\mu$ SOF packets other than  $\mu$ FRNM = 000 are received normally.

### 23.4.10 Pipe Schedule

#### (1) Conditions for Generating a Transaction

When the host controller function is selected and UACT has been set to 1, this module generates a transaction under the conditions noted in table 23.27.

**Table 23.27 Conditions for Generating a Transaction**

| Transaction                                                 | Conditions for Generation |                 |                 |                        |                 |
|-------------------------------------------------------------|---------------------------|-----------------|-----------------|------------------------|-----------------|
|                                                             | DIR                       | PID             | IITV0           | Buffer State           | SUREQ           |
| Setup                                                       | —* <sup>1</sup>           | —* <sup>1</sup> | —* <sup>1</sup> | —* <sup>1</sup>        | 1 setting       |
| Control transfer data stage,<br>status stage, bulk transfer | IN                        | BUF             | Invalid         | Receive<br>area exists | —* <sup>1</sup> |
|                                                             | OUT                       | BUF             | Invalid         | Send data<br>exists    | —* <sup>1</sup> |
| Interrupt transfer                                          | IN                        | BUF             | Valid           | Receive<br>area exists | —* <sup>1</sup> |
|                                                             | OUT                       | BUF             | Valid           | Send data<br>exists    | —* <sup>1</sup> |
| Isochronous transfer                                        | IN                        | BUF             | Valid           | * <sup>2</sup>         | —* <sup>1</sup> |
|                                                             | OUT                       | BUF             | Valid           | * <sup>3</sup>         | —* <sup>1</sup> |

- Notes:
1. Symbols (—) in the table indicate that the condition is one that is unrelated to the generating of tokens. “Valid” indicates that, for interrupt transfers and isochronous transfers, the condition is generated only in transfer frames that are based on the interval counter. “Invalid” indicates that the condition is generated regardless of the interval counter.
  2. This indicates that a transaction is generated regardless of whether or not there is a receive area. If there was no receive area, however, the received data is destroyed.
  3. This indicates that a transaction is generated regardless of whether or not there is any data to be sent. If there was no data to be sent, however, a zero-length packet is sent.

## (2) Transfer Schedule

This section describes the transfer scheduling within a frame of this module. After the module sends an SOF, the transfer is carried out in the sequence described below.

### 1. Execution of periodic transfers

A pipe is searched in the order of Pipe 1 → Pipe 2 → Pipe 6 → Pipe 7, and then, if the pipe is one for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.

### 2. Setup transactions for control transfers

The DCP is checked, and if a setup transaction is possible, it is sent.

### 3. Execution of bulk and control transfer data stages and status stages

A pipe is searched in the order of DCP → Pipe 1 → Pipe 2 → Pipe 3 → Pipe 4 → Pipe 5, and then, if the pipe is one for which a bulk or control transfer data stage or a control transfer status stage transaction can be generated, the transaction is generated.

If a transfer is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral is ACK or NAK. Also, if there is time for the transfer to be done within the frame, step 3 is repeated.

## (3) USB Communication Enabled

Setting the UACT bit of the DVSTCTR register to 1 initiates sending of an SOF or  $\mu$ SOF, and makes it possible to generate a transaction.

Setting the UACT bit to 0 stops the sending of the SOF or  $\mu$ SOF and initiates a suspend state. If the setting of the UACT bit is changed from 1 to 0, processing stops after the next SOF or  $\mu$ SOF is sent.

## 23.5 Usage Notes

### 23.5.1 Note on Using Isochronous OUT Transfer

When the following conditions (1 and 2) are met, use the pipe settings in the table below for isochronous (hereinafter referred to as ISO)-OUT transfer.

1. Host mode is in use
2. Full-speed transfer

**Note:** This note does not apply when high-speed transfer in host mode has been selected or function mode (including the selection of full-speed transfer) is used.

|                                     | <b>PIPE1</b>                   | <b>PIPE2</b>          | <b>PIPE6</b>         |
|-------------------------------------|--------------------------------|-----------------------|----------------------|
| ISO-OUT transfer is in use on PIPE1 | ISO-OUT                        | Unused or BULK-IN/OUT | Unused or INT-IN/OUT |
| ISO-OUT transfer is in use on PIPE2 | Unused, ISO-IN, or BULK-IN/OUT | ISO-OUT               | Unused               |

**Note:** ISO-OUT transfer cannot be used on both PIPE1 and PIPE2 (two pipes). When two pipes would be needed for ISO-OUT transfer, use high-speed transfer.

### 23.5.2 Procedure for Setting the USB Transceiver

The internal USB transceiver must be set up before this module can be used. The procedure is described below. Furthermore, figure 23.20 gives an example of a program that implements the procedure.

1. Write 1 to the UACS23 bit in the USB AC characteristics switching register.
2. Write 1 to the HOSTPCC bit in the test mode register (TESTMODE).

A special sequence can be used to ensure that these bits are not erroneously overwritten. The sequence for writing is given below.

1. Write 1 to the UACKEY0 and UACKEY1 bits in the device control register (DVSTCTR).
2. Write 1 to the HOSTPCC bit in the test mode register (TESTMODE).
3. Write 0 to the UACKEY0 and UACKEY1 bits in the device control register (DVSTCTR).

```

;Initialization routine
;Set USBE = 1
    MOV.I20 #H'FFFC1C00, R0
    MOV.W #H'0001, R1
    MOV.W R1, @R0

;(1) Set UACS23 = 1
    MOV.I20 #H'FFFC1C84, R0
    MOV.L #H'00800000, R1
    MOV.L R1, @R0

;(2) Set HOSTPCC = 1
;1. UACKEY0, UACKEY1 = 1
    MOV.I20 #H'FFFC1C04, R0
    MOV.W #H'9000, R1
    MOV.W R1, @R0
;2. HOSTPCC = 1
    MOV.I20 #H'FFFC1C06, R0
    MOV.W #H'8000, R1
    MOV.W R1, @R0
;3. UACKEY0, UACKEY1 = 0
    MOV.I20 #H'FFFC1C04, R0
    MOV.W #H'0000, R1
    MOV.W R1, @R0
    .
    .
    .
    .

```

**Figure 23.20 Procedure for Setting the USB Transceiver**

### 23.5.3 Timing for the Clearing of Interrupt Sources

The interrupt source flags should be cleared in the interrupt exception service routine. After clearing the interrupt source flag, a certain amount of time is required until the interrupt source sent to the CPU is actually cancelled. To ensure that an interrupt request that should have been cleared is not inadvertently accepted again, read the interrupt source flag three times after it has been cleared, and then execute an RTE instruction.

## Section 24 LCD Controller (LCDC)

A unified memory architecture is adopted for the LCD controller (LCDC) so that the image data for display is stored in system memory. The LCDC module reads data from system memory, uses the palette memory to determine the colors, then puts the display on the LCD panel. It is possible to connect the LCDC to the LCD module\* other than microcomputer bus interface types and NTSC/PAL types and those that apply the LVDS interface.

Note: \* LCD module can be connected to the LVDS interface by using the LSI with LVDS conversion LSI.

### 24.1 Features

The LCDC has the following features.

- Panel interface
  - Serial interface method
  - Supports data formats for STN/dual-STN/TFT panels (8/12/16/18-bit bus width)\*<sup>1</sup>
- Supports 4/8/15/16-bpp (bits per pixel) color modes
- Supports 1/2/4/6-bpp grayscale modes
- Supports LCD-panel sizes from  $16 \times 1$  to  $1024 \times 1024$ \*<sup>2</sup>
- 24-bit color palette memory (16 of the 24 bits are valid; R:5/G:6/B:5)
- STN/DSTN panels are prone to flicker and shadowing. The controller applies 65536-color control by 24-bit space-modulation FRC with 8-bit RGB values for reduced flicker.
- Dedicated display memory is unnecessary using part of the synchronous DRAM (area 3) as the VRAM to store display data of the LCDC.
- The display is stable because of the large 2.4-kbyte line buffer
- Supports the inversion of the output signal to suit the LCD panel's signal polarity
- Supports the selection of data formats (the endian setting for bytes, backed pixel method) by register settings
- An interrupt can be generated at the user specified position (controlling the timing of VRAM update start prevents flicker)
- A hardware-rotation mode is included to support the use of landscape-format LCD panels as portrait-format LCD panels (the horizontal width of the panel before rotation must be within 320 pixels (see table 24.5.)

Notes: 1. When connecting the LCDC to a TFT panel with an unwired 18-bit bus, the lower bit lines should be connected to GND or to the lowest bit from which data is output.  
2. For details, see section 24.4.1, LCD Module Sizes which can be Displayed in this LCDC.

Figure 24.1 shows a block diagram of LCDC.

**Figure 24.1 LCDC Block Diagram**

## 24.2 Input/Output Pins

Table 24.1 summarizes the LCDC's pin configuration.

**Table 24.1 Pin Configuration**

| Pin Name        | I/O    | Function                                                      |
|-----------------|--------|---------------------------------------------------------------|
| LCD_DATA15 to 0 | Output | Data for LCD panel                                            |
| LCD_DON         | Output | Display-on signal (DON)                                       |
| LCD_CL1         | Output | Shift-clock 1 (STN/DSTN)/horizontal sync signal (HSYNC) (TFT) |
| LCD_CL2         | Output | Shift-clock 2 (STN/DSTN)/dot clock (DOTCLK) (TFT)             |
| LCD_M_DISP      | Output | LCD current-alternating signal/DISP signal                    |
| LCD_FLM         | Output | First line marker/vertical sync signal (VSYNC) (TFT)          |
| LCD_VCPWC       | Output | LCD-module power control (VCC)                                |
| LCD_VEPWC       | Output | LCD-module power control (VEE)                                |
| LCD_CLK         | Input  | LCD clock-source input                                        |

Note: Check the LCD module specifications carefully in section 24.5, Clock and LCD Data Signal Examples, before deciding on the wiring specifications for the LCD module.

## 24.3 Register Configuration

The LCDC includes the following registers. For description on the address and processing status of these registers, refer to section 30, List of Registers. The setting to LDSARU and LDSARL are updated with the Vsync timing when the LCDC is active.

**Table 24.2 Register Configuration**

| Register Name                                                  | Abbreviation     | R/W | Initial Value | Address                    | Access Size |
|----------------------------------------------------------------|------------------|-----|---------------|----------------------------|-------------|
| LCDC input clock register                                      | LDICKR           | R/W | H'0101        | H'FFFFFFC00                | 16          |
| LCDC module type register                                      | LDMTR            | R/W | H'0109        | H'FFFFFFC02                | 16          |
| LCDC data format register                                      | LDDFR            | R/W | H'000C        | H'FFFFFFC04                | 16          |
| LCDC scan mode register                                        | LDSMR            | R/W | H'0000        | H'FFFFFFC06                | 16          |
| LCDC data fetch start address register for upper display panel | LDSARU           | R/W | H'0C000000    | H'FFFFFFC08                | 32          |
| LCDC data fetch start address register for lower display panel | LDSARL           | R/W | H'0C000000    | H'FFFFFFC0C                | 32          |

### 24.3.1 LCDC Input Clock Register (LDICKR)

This LCDC can select bus clock, the peripheral clock, or the external clock as its operation clock source. The selected clock source can be divided using an internal divider into a clock of 1/1 to 1/32 and be used as the LCDC operating clock (DOTCLK). The clock output from the LCDC is used to generate the synchronous clock output (LCD\_CL2) for the LCD panel from the operating clock selected in this register. For a TFT panel, LCD\_CL2 = DOTCLK. For an STN or DSTN panel, the following clock is output to LCD\_CL2:

- Monochrome: LCD\_CL2 = (DOTCLK / output data bus width to LCD panel) frequency
- Color: LCD\_CL2 = (DOTCLK × 3 / output data bus width to LCD panel) frequency

However, since the frequency is 1/nth of DOTCLK where n is an integer value, some cycles may not be output to LCD\_CL2 when the value is not divisible without a remainder.

For details of LCD\_CL2 timing, see figures 24.11 to 24.22. The LDICKR must be set so that the clock input to the LCDC is 66 MHz or less regardless of the LCD\_CL2.

| 000011    | 1/3                  | 16.667                    | 20.000 | 22.000 |
| 000100    | 1/4                  | 12.500                    | 15.000 | 16.500 |
| 000110    | 1/6                  | 8.333                     | 10.000 | 11.000 |
| 001000    | 1/8                  | 6.250                     | 7.500  | 8.250  |
| 001100    | 1/12                 | 4.167                     | 5.000  | 5.500  |
| 010000    | 1/16                 | 3.125                     | 3.750  | 4.125  |
| 011000    | 1/24                 | 2.083                     | 2.500  | 2.750  |
| 100000    | 1/32                 | 1.563                     | 1.875  | 2.063  |

Note: Any setting other than above is handled as a clock division ratio of 1/1 (initial value).

### 24.3.2 LCDC Module Type Register (LDMTR)

LDMTR sets the control signals output from this LCDC and the polarity of the data signals, according to the polarity of the signals for the LCD module connected to the LCDC.

|--------|-------------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5 to 0 | MIFTYP[5:0] | 001001        | R/W | <p>Module Interface Type Select</p> <p>Set the LCD panel type and data bus width to be output to the LCD panel. There are three LCD panel types: STN, DSTN, and TFT. There are four data bus widths for output to the LCD panel: 4, 8, 12, and 16 bits. When the required data bus width for a TFT panel is 16 bits or more, connect the LCDC and LCD panel according to the data bus size of the LCD panel. Unlike in a TFT panel, in an STN or DSTN panel, the data bus width setting does not have a 1:1 correspondence with the number of display colors and display resolution, e.g., an 8-bit data bus can be used for 16 bpp, and a 12-bit data bus can be used for 4 bpp. This is because the number of display colors in an STN or DSTN panel is determined by how data is placed on the bus, and not by the number of bits. For data specifications for an STN or DSTN panel, see the specifications of the LCD panel used. The output data bus width should be set according to the mechanical interface specifications of the LCD panel.</p> <p>If an STN or DSTN panel is selected, display control is performed using a 24-bit space-modulation FRC consisting of the 8-bit R, G, and B included in the LCDC, regardless of the color and gradation settings. Accordingly, the color and gradation specified by DSPCOLOR is selected from 16 million colors in an STN or DSTN panel. If a palette is used, the color specified in the palette is displayed.</p> <p>000000: STN monochrome 4-bit data bus module<br/> 000001: STN monochrome 8-bit data bus module<br/> 001000: STN color 4-bit data bus module<br/> 001001: STN color 8-bit data bus module<br/> 001010: STN color 12-bit data bus module<br/> 001011: STN color 16-bit data bus module<br/> 010001: DSTN monochrome 8-bit data bus module<br/> 010011: DSTN monochrome 16-bit data bus module<br/> 011001: DSTN color 8-bit data bus module<br/> 011010: DSTN color 12-bit data bus module<br/> 011011: DSTN color 16-bit data bus module<br/> 101011: TFT color 16-bit data bus module</p> <p>Settings other than above: Setting prohibited</p> |

### 24.3.3 LCDC Data Format Register (LDDFR)

LDDFR sets the bit alignment for pixel data in one byte and selects the data type and number of colors used for display so as to match the display driver software specifications.

### 24.3.5 LCDC Start Address Register for Upper Display Data Fetch (LDSARU)

LDSARU sets the start address from which data is fetched by the LCDC for display of the LCDC panel. When a DSTN panel is used, this register specifies the fetch start address for the upper side of the panel. The register setting is updated with the Vsync timing when the LCDC is active.

- Notes:
1. The minimum alignment unit of LDSARU is 512 bytes when the hardware rotation function is not used. Write 0 to the lower nine bits. When using the hardware rotation function, set the LDSARU value so that the upper-left address of the image is aligned with the 512-byte boundary.
  2. When the hardware rotation function is used (ROT = 1), set the upper-left address of the image which can be calculated from the display image size in this register. The equation below shows how to calculate the LDSARU value when the image size is 240 × 320 and LDLAOR = 256. The LDSARU value is obtained not from the panel size but from the memory size of the image to be displayed. Note that LDLAOR must be a binary exponential at least as large as the horizontal width of the image. Calculate backwards using the LDSARU value (LDSARU – 256 (LDLAOR value) × (320 – 1)) to ensure that the upper-left address of the image is aligned with the 512-byte boundary.  

$$\text{LDSARU} = (\text{upper-left address of image}) + 256 (\text{LDLAOR value}) \times 319 (\text{line})$$

### 24.3.6 LCDC Start Address Register for Lower Display Data Fetch (LDSARL)

When a DSTN panel is used, LDSARL specifies the fetch start address for the lower side of the panel. The register setting is updated with the Vsync timing when the LCDC is active.

### 24.3.7 LCDC Line Address Offset Register for Display Data Fetch (LDLAOR)

LDLAOR sets the address width of the Y-coordinates increment used for LCDC to read the image recognized by the graphics driver. This register specifies how many bytes the address from which data is to be read should be moved when the Y coordinates have been incremented by 1. This register does not have to be equal to the horizontal width of the LCD panel. When the memory address of a point (X, Y) in the two-dimensional image is calculated by  $Ax + By + C$ , this register becomes equal to B in this equation.

| 9        | LAO9           | 1             | R/W | <p>The minimum alignment unit of LDLAOR is 16 bytes. Because the LCDC handles these values as 16-byte data, the values written to the lower four bits of the register are always treated as 0. The lower four bits of the register are always read as 0. The initial values (<math>\times</math> resolution = 640) will continuously and accurately place the VGA (640 <math>\times</math> 480 dots) display data without skipping an address between lines. For details, see tables 24.4 and 24.5.</p> <p>A binary exponential at least as large as the horizontal width of the image is recommended for the LDLAOR value, taking into consideration the software operation speed. When the hardware rotation function is used, the LDLAOR value should be a binary exponential (in this example, 256) at least as large as the horizontal width of the image (after rotation, it becomes 240 in a 240 <math>\times</math> 320 panel) instead of the horizontal width of the LCD panel (320 in a 320 <math>\times</math> 240 panel).</p> |

### 24.3.8 LCDC Palette Control Register (LDPALCR)

LDPALCR selects whether the CPU or LCDC accesses the palette memory. When the palette memory is being used for display operation, display mode should be selected. When the palette memory is being written to, color-palette setting mode should be selected.

24.3.9 Palette Data Registers 00 to FF (LDPR00 to LDPRFF)

LDPR registers are for accessing palette data directly allocated (4 bytes × 256 addresses) to the memory space. To access the palette memory, access the corresponding register among this register group (LDPR00 to LDPRFF). Each palette register is a 32-bit register including three 8-bit areas for R, G, and B. For details on the color palette specifications, see section 24.4.3, Color Palette Specification.

### 24.3.10 LCDC Horizontal Character Number Register (LDHCNR)

LDHCNR specifies the LCD module's horizontal size (in the scan direction) and the entire scan width including the horizontal retrace period.

| 8   | HDCN0    | 1             | R/W |                                                                                                                                                                                                           |
| 7   | HTCN7    | 0             | R/W | Horizontal Total Character Number                                                                                                                                                                         |
| 6   | HTCN6    | 1             | R/W | Set the number of total horizontal characters (unit: character = 8 dots).                                                                                                                                 |
| 5   | HTCN5    | 0             | R/W |                                                                                                                                                                                                           |
| 4   | HTCN4    | 1             | R/W | Specify to the value of (the number of total characters) - 1.                                                                                                                                             |
| 3   | HTCN3    | 0             | R/W |                                                                                                                                                                                                           |
| 2   | HTCN2    | 0             | R/W | However, the minimum horizontal retrace period is three characters (24 dots).                                                                                                                             |
| 1   | HTCN1    | 1             | R/W |                                                                                                                                                                                                           |
| 0   | HTCN0    | 0             | R/W | Example: For a LCD module with a width of 640 pixels.<br>HTCN = [(640/8)-1] +3 = 82 = H'52<br>In this case, the number of total horizontal dots is 664 dots and the horizontal retrace period is 24 dots. |

- Notes: 1. The values set in HDCN and HTCN must satisfy the relationship of  $HTCN \geq HDCN$ . Also, the total number of characters of HTCN must be an even number. (The set value will be an odd number, as it is one less than the actual number.)
2. Set HDCN according to the display resolution as follows:
- 1 bpp: (multiple number of 16) - 1 [1 line is multiple number of 128 pixel]
  - 2 bpp: (multiple number of 8) - 1 [1 line is multiple number of 64 pixel]
  - 4 bpp: (multiple number of 4) - 1 [1 line is multiple number of 32 pixel]
  - 6 bpp/8 bpp: (multiple number of 2) - 1 [1 line is multiple number of 16 pixel]

### 24.3.11 LCDC Horizontal Sync Signal Register (LDHSYNR)

LDHSYNR specifies the timing of the generation of the horizontal (scan direction) sync signals for the LCD module.

Note: The following conditions must be satisfied:

$$\text{HTCN} \geq \text{HSYNP} + \text{HSYNW} + 1$$

$$\text{HSYNP} \geq \text{HDCN} + 1$$

### 24.3.12 LCDC Vertical Display Line Number Register (LDVDLNR)

LDVDLNR specifies the LCD module's vertical size (for both scan direction and vertical direction). For a DSTN panel, specify an even number at least as large as the LCD panel's vertical size regardless of the size of the upper and lower panels, e.g. 480 for a 640 x 480 panel.

|                |    |    |    |    |    |        |       |       |       |       |       |       |       |       |       |       |

### 24.3.15 LCDC AC Modulation Signal Toggle Line Number Register (LDACLNR)

LDACLNR specifies the timing to toggle the AC modulation signal (LCD current-alternating signal) of the LCD module.

|                |    |    |    |    |    |    |   |   |   |   |   |       |       |       |       |       |

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                 |
|---------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------|
| 15 to 5 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                            |
| 4       | ACLN4    | 0             | R/W | AC Line Number                                                                                              |
| 3       | ACLN3    | 1             | R/W | Set the number of lines where the LCD current-alternating signal of the LCD module is toggled (unit: line). |
| 2       | ACLN2    | 1             | R/W |                                                                                                             |
| 1       | ACLN1    | 0             | R/W | Specify to the value of (the number of toggle line) -1.                                                     |
| 0       | ACLN0    | 0             | R/W | Example: For toggling every 13 lines.<br>$\text{ACLN} = 13 - 1 = 12 = \text{H}'0\text{C}$                   |

Note: When the total line number of the LCD panel is even, set an even number so that toggling is performed at an odd line.

### 24.3.16 LCDC Interrupt Control Register (LDINTR)

LDINTR specifies where to control the Vsync interrupt of the LCD module. See also section 24.3.20, LCDC User Specified Interrupt Control Register (LDUINTR) and section 24.3.21, LCDC User Specified Interrupt Line Number Register (LDUINTLNR) for interrupts. Note that operations by this register setting and LCDC user specified interrupt control register (LDUINTR) setting are independent.

### 24.3.17 LCDC Power Management Mode Register (LDPMMR)

LDPMMR controls the power supply circuit that provides power to the LCD module. The usage of two types of power-supply control pins, LCD\_VCPWC and LCD\_VEPWC, and turning on or off the power supply function are selected.

### 24.3.18 LDCD Power-Supply Sequence Period Register (LDPSPR)

LDPSPR controls the power supply circuit that provides power to the LCD module. The timing to start outputting the timing signals to the LCD\_VEPWC and LCD\_VCPWC pins is specified.

### 24.3.19 LCDC Control Register (LDCNTR)

LDCNTR specifies start and stop of display by the LCDC.

When 1s are written to the DON2 bit and the DON bit, the LCDC starts display. Turn on the LCD module following the sequence set in the LDPMMR and LDPSPR. The sequence ends when the LPS[1:0] value changes from B'00 to B'11. Do not make any action to the DON bit until the sequence ends.

When 0 is written to the DON bit, the LCDC stops display. Turn off the LCD module following the sequence set in the LDPMMR and LDPSPR. The sequence ends when the LPS[1:0] value changes from B'11 to B'00. Do not make any action to the DON bit until the sequence ends.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                       |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | DON      | 0             | R/W | <p>Display On</p> <p>Specifies the start and stop of the LCDC display operation.</p> <p>The control sequence state can be checked by referencing the LPS[1:0] of LDPMMR.</p> <p>0: Display-off mode: LCDC is stopped</p> <p>1: Display-on mode: LCDC operates</p> |

- Notes:
1. Write H'0011 to LDCNTR to start display output and H'0000 to end display output. Data other than H'0011 and H'0000 must not be written here.
  2. Setting bit DON2 to 1 makes the contents of the palette RAM undefined. Before writing to the palette RAM, set bit DON2 to 1.
  3. To access another register of the LCDC after writing to LDCNTR, wait for at least four cycles of  $P\phi$  or dummy-read STBCR4 once beforehand.

### 24.3.20 LCDC User Specified Interrupt Control Register (LDUINTR)

LDUINTR sets whether the user specified interrupt is generated, and indicates its processing state. This interrupt is generated at the time when image data which is set by the line number register (LDUINTLNR) in LCDC is read from VRAM.

This LCDC issues the interrupts (LCDCI): user specified interrupt by this register, memory access interrupt by the LCDC interrupt control register (LDINTR), and OR of Vsync interrupt output. This register and LCDC interrupt control register (LDINTR) settings affect the interrupt operation independently.

| 0      | UINTS    | 0             | R/W | <p>User Specified Interrupt State</p> <p>This bit is set to 1 at the time an LCDC user specified interrupt is generated (set state). During the user specified interrupt handling routine, this bit should be cleared by writing 0 to it.</p> <p>0: LCDC did not generate a user specified interrupt or has been informed that the generated user specified interrupt has completed</p> <p>1: LCDC has generated a user specified interrupt and has not yet been notified that the generated user specified interrupt has completed</p> |

Notes: Interrupt processing flow:

1. Interrupt signal is input
2. LDINTR is read
3. If MINTS, FINTS, VSINTS, or VEINTS is 1, a generated interrupt is memory access interrupt, flame end interrupt, Vsync rising edge interrupt, or Vsync falling edge interrupt. Processing for each interrupt is performed.
4. If MINTS, FINTS, VSINTS, or VEINTS is 0, a generated interrupt is not memory access interrupt, flame end interrupt, Vsync rising edge interrupt, or Vsync falling edge interrupt.
5. UINTS is read.
6. If UINTS is 1, a generated interrupt is a user specified interrupt. Process for user specified interrupt is carried out.
7. If UINTS is 0, a generated interrupt is not a user specified interrupt. Other processing is performed.

### 24.3.21 LCDC User Specified Interrupt Line Number Register (LDUINTLNR)

LDUINTLNR sets the point where the user specified interrupt is generated. Setting is done in horizontal line units.

| 3        | UINTLN3  | 1             | R/W |                                                                                     |
| 2        | UINTLN2  | 1             | R/W |                                                                                     |
| 1        | UINTLN1  | 1             | R/W |                                                                                     |
| 0        | UINTLN0  | 1             | R/W |                                                                                     |

- Notes:
1. When using the LCD module with STN/TFT display, the setting value of this register should be equal to lower than the vertical display line number (VDLN) in LDVDLNR.
  2. When using the LCD module with DSTN display, the setting value of this register should be equal to or lower than half the vertical display line number (VDLN) in LDVDLNR. The user specified interrupt is generated at the point when the LCDC read the specified piece of image data in lower display from VRAM.

### 24.3.22 LCDC Memory Access Interval Number Register (LDLIRNR)

LDLIRNR controls the bus clock interval when the LCDC reads VRAM. As the LCDC does not access VRAM during the bus clock period specified by LDLIRNR, external bus accesses by the CPU or the DMAC is possible during that period.

## 24.4 Operation

### 24.4.1 LCD Module Sizes which Can Be Displayed in this LCDC

This LCDC is capable of controlling displays with up to  $1024 \times 1024$  dots and 16 bpp (bits per pixel). The image data for display is stored in VRAM, which is shared with the CPU. This LCDC should read the data from VRAM before display.

This LSI has a maximum 32-burst memory read operation and a 2.4-kbyte line buffer, so although a complete breakdown of the display is unlikely, there may be some problems with the display depending on the combination.

As a rough standard, the bus occupation ratio shown below should not exceed 40%.

$$\text{Bus occupation ratio (\%)} = \frac{\text{Overhead coefficient} \times \text{Total number of display pixels } ((\text{HDCN} + 1) \times 8 \times (\text{VDLN} + 1))}{\text{Frame rate (Hz)} \times \text{Number of colors (bpp)}} \times 100$$

$$\text{Bus occupation ratio (\%)} = \frac{\text{Overhead coefficient} \times \text{Total number of display pixels } ((\text{HDCN} + 1) \times 8 \times (\text{VDLN} + 1))}{\text{CKIO (Hz)} \times \text{Bus width (bit)}} \times 100$$

The overhead coefficient becomes 1.375 when the CL2 SDRAM is connected to a 32-bit data bus and 1.188 when connected to a 16-bit data bus.

Figure 24.2 shows the valid display and the retrace period.

**Figure 24.2 Valid Display and the Retrace Period**

#### 24.4.2 Limits on the Resolution of Rotated Displays, Burst Length, and Connected Memory (SDRAM)

This LCDC is capable of displaying a landscape-format image on a LCD module by rotating a portrait format image for display by 90 degrees. Only the numbers of colors for each resolution are supported as shown in tables 24.4 and 24.5. The size of the SDRAM (the number of column address bits) and its burst length are limited to read the SDRAM continuously.

The number of colors for display, SDRAM column addresses, and LCDC burst length are shown tables 24.4 and 24.5.

A monochromatic LCD module is necessary for the display of images in the above monochromatic formats. A color LCD module is necessary for the display of images in the above color formats.

**Table 24.4 Limits on the Resolution of Rotated Displays, Burst Length, and Connected Memory (32-bit SDRAM)**

| Image for Display in Memory<br>(X-Resolution × Y-Resolution) | LCD Module<br>(X-Resolution × Y-Resolution) | Number of Colors for Display |                  | Number of Column Address Bits of SDRAM | Burst Length of LCDC (LDSMR*) |
|--------------------------------------------------------------|---------------------------------------------|------------------------------|------------------|----------------------------------------|-------------------------------|
| 240 × 320                                                    | 320 × 240                                   | Monochrome                   | 4 bpp (packed)   | 8 bits                                 | Not more than 8 bursts        |

|                                                              |                                             |                              |                  | 10 bits                                | —                             |

Note: \* Specify the data so that the data of the number of line specified as burst length can be stored in the same ROW address of SDRAM.

24.4.3 Color Palette Specification

**Color Palette Register:** This LCDC has a color palette which outputs 24 bits of data per entry and is able to simultaneously hold 256 entries. The color palette thus allows the simultaneous display of 256 colors chosen from among 16-M colors.

The procedure below may be used to set up color palettes at any time.

- 1. The PALEN bit in the LDPALCR is 0 (initial value); normal display operation
- 2. Access LDPALCR and set the PALEN bit to 1; enter color-palette setting mode after three cycles of peripheral clock.
- 3. Access LDPALCR and confirm that the PALS bit is 1.
- 4. Access LDPR00 to LDPRFF and write the required values to the PALD00 to PALDFF bits.
- 5. Access LDPALCR and clear the PALEN bit to 0; return to normal display mode after a cycle of peripheral clock.

A 0 is output on the LCDC display data output (LCD\_DATA) while the PALS bit in LDPALCR is set to 1.

Figure 24.3 Color-Palette Data Format

PALDnn color and gradation data should be set as above.

For a color display, PALDnn[23:16], PALDnn[15:8], and PALDnn[7:0] respectively hold the R, G, and B data. Although the bits PALDnn[18:16], PALDnn[9:8], and PALDnn[2:0] exist, no memory is associated with these bits. PALDnn[18:16], PALDnn[9:8], and PALDnn[2:0] are thus not available for storing palette data. The numbers of valid bits are thus R: 5, G: 6, and B: 5. A 24-bit (R: 8 bits, G: 8 bits, and B: 8 bits) data should, however, be written to the palette-data registers. When the values for PALDnn[23:19], PALDnn[15:10], or PALDnn[7:3] are not 0, 1 or 0 should be written to PALDnn[18:16], PALDnn[9:8], or PALDnn[2:0], respectively. When the values of PALDnn[23:19], PALDnn[15:10], or PALDnn[7:3] are 0, 0s should be written to PALDnn[18:16], PALDnn[9:8], or PALDnn[2:0], respectively. Then 24 bits are extended.

Grayscale data for a monochromatic display should be set in PALDnn[7:3]. PALDnn[23:8] are all "don't care". When the value in PALDnn[7:3] is not 0, 1s should be written to PALDnn[2:0]. When the value in PALDnn[7:3] is 0, 0s should be written to PALDnn[2:0]. Then 8 bits are extended.

## 24.4.4 Data Format

### 1. Packed 1bpp (Pixel Alignment in Byte is Big Endian) [Windows CE Recommended Format]

| Address | MSB            |     |     |     | LSB |     |     |     | [Bit]   |
|---------|----------------|-----|-----|-----|-----|-----|-----|-----|---------|
|         | 7              | 6   | 5   | 4   | 3   | 2   | 1   | 0   |         |
| +00     | P00            | P01 | P02 | P03 | P04 | P05 | P06 | P07 | (Byte0) |
| +01     | P08            |     |     |     |     |     |     |     | (Byte1) |
| +02     |                |     |     |     |     |     |     |     |         |
| +03     |                |     |     |     |     |     |     |     |         |
| ...     | ...            |     |     |     |     |     |     |     |         |

### 24.4.5 Setting the Display Resolution

The display resolution is set up in LDHCNR, LDHSYNR, LDVDLNR, LDVTLNR, and LDVSYNR. The LCD current-alternating period for an STN or DSTN display is set by using the LDACLNR. The initial values in these registers are typical settings for VGA (640 × 480 dots) on an STN or DSTN display.

The clock to be used is set with the LDICKR. The LCD module frame rate is determined by the display interval + retrace line interval (non-display interval) for one screen set in a size related register and the frequency of the clock used.

This LCDC has a Vsync interrupt function so that it is possible to issue an interrupt at the beginning of each vertical retrace line period (to be exact, at the beginning of the line after the last line of the display). This function is set up by using the LDINTR.

### 24.4.6 Power Management Registers

An LCD module normally requires a specific sequence for processing to do with the cutoff of the input power supply. Settings in LDPMMR, LDPSPR, and LDCNTR, in conjunction with the LCD power-supply control pins (LCD\_VCPWC, LCD\_VEPWC, and LCD\_DON), are used to provide processing of power-supply control sequences that suits the requirements of the LCD module.

Figure 24.4 gives the flowcharts for power-supply control sequences, figures 24.5 to 24.8 are summary timing charts for the power-supply control sequences, and table 24.6 is a summary of the available power-supply control sequence periods.

## (1) Power-on sequence (when EXTAL is selected as the input clock)

## (2) Power-on sequence (when the bus clock or the peripheral clock is selected as the input clock)

## (3) Power-off sequence

| ONX, OFFX Register Value | Frame Rate                         |                                   |
|--------------------------|------------------------------------|-----------------------------------|
|                          | 120 Hz                             | 60 Hz                             |
| H'F                      | $(-1+1)/120 = 0.00 \text{ (ms)}$   | $(-1+1)/60 = 0.00 \text{ (ms)}$   |
| H'0                      | $(0+1)/120 = 8.33 \text{ (ms)}$    | $(0+1)/60 = 16.67 \text{ (ms)}$   |
| H'1                      | $(1+1)/120 = 16.67 \text{ (ms)}$   | $(1+1)/60 = 33.33 \text{ (ms)}$   |
| H'2                      | $(2+1)/120 = 25.00 \text{ (ms)}$   | $(2+1)/60 = 50.00 \text{ (ms)}$   |
| H'3                      | $(3+1)/120 = 33.33 \text{ (ms)}$   | $(3+1)/60 = 66.67 \text{ (ms)}$   |
| H'4                      | $(4+1)/120 = 41.67 \text{ (ms)}$   | $(4+1)/60 = 83.33 \text{ (ms)}$   |
| H'5                      | $(5+1)/120 = 50.00 \text{ (ms)}$   | $(5+1)/60 = 100.00 \text{ (ms)}$  |
| H'6                      | $(6+1)/120 = 58.33 \text{ (ms)}$   | $(6+1)/60 = 116.67 \text{ (ms)}$  |
| H'7                      | $(7+1)/120 = 66.67 \text{ (ms)}$   | $(7+1)/60 = 133.33 \text{ (ms)}$  |
| H'8                      | $(8+1)/120 = 75.00 \text{ (ms)}$   | $(8+1)/60 = 150.00 \text{ (ms)}$  |
| H'9                      | $(9+1)/120 = 83.33 \text{ (ms)}$   | $(9+1)/60 = 166.67 \text{ (ms)}$  |
| H'A                      | $(10+1)/120 = 91.67 \text{ (ms)}$  | $(10+1)/60 = 183.33 \text{ (ms)}$ |
| H'B                      | $(11+1)/120 = 100.00 \text{ (ms)}$ | $(11+1)/60 = 200.00 \text{ (ms)}$ |
| H'C                      | $(12+1)/120 = 108.33 \text{ (ms)}$ | $(12+1)/60 = 216.67 \text{ (ms)}$ |
| H'D                      | $(13+1)/120 = 116.67 \text{ (ms)}$ | $(13+1)/60 = 233.33 \text{ (ms)}$ |
| H'E                      | $(14+1)/120 = 125.00 \text{ (ms)}$ | $(14+1)/60 = 250.00 \text{ (ms)}$ |

ONA, ONB, ONC, OFFD, OFFE, and OFFF are used to set the power-supply control-sequence periods, in units of frames, from 0 to 15. 1 is subtracted from each register. H'0 to H'E settings select from 1 to 15 frames. The setting H'F selects 0 frames.

Actual sequence periods depend on the register values and the frame frequency of the display. The following table gives power-supply control-sequence periods for display frame frequencies used by typical LCD modules.

- When ONB is set to H'6 and display's frame frequency is 120 Hz  
 The display's frame frequency is 120 Hz. 1 frame period is thus  $8.33 \text{ (ms)} = 1/120 \text{ (sec)}$ .  
 The power-supply input sequence period is 7 frames because ONB setting is subtracted by 1.  
 As a result, the sequence period is  $58.33 \text{ (ms)} = 8.33 \text{ (ms)} \times 7$ .

**Table 24.7 LCDC Operating Modes**

| <b>Mode</b>                   |                           | <b>Function</b>                                                                                                                                                                     |
|-------------------------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Display on<br>(LCDC active)   | Register setting: DON = 1 | Fixed resolution, the format of the data for display is determined by the number of colors, and timing signals are output to the LCD module.                                        |
| Display off<br>(LCDC stopped) | Register setting: DON = 0 | Register access is enabled.<br><br>Fixed resolution, the format of the data for display is determined by the number of colors, and timing signals are not output to the LCD module. |

|                      | Supply                        |                                                             |                                              |                   |
| Stopped State        |                               |                                                             |                                              |                   |

(TFT module)

| State                | Power Supply for Logic | Display Data, Timing Signal                     | Power Supply for High-Voltage Systems |
|----------------------|------------------------|-------------------------------------------------|---------------------------------------|
| Control Pin          | LCD_VCPWC              | LCD_CL2, LCD_CL1, LCD_FLM, LCD_M_DISP, LCD_DATA | LCD_VEPWC                             |
| Operating State      | Supply                 | Supply                                          | Supply                                |
| (Transitional State) | Supply                 | Supply                                          |                                       |
|                      | Supply                 |                                                 |                                       |
| Stopped State        |                        |                                                 |                                       |

The table above shows the states of the power supply, display data, and timing signals for the typical LCD module in its active and stopped states. Some of the supply voltages described may not be necessary, because some modules internally generate the power supply required for high-voltage systems from the logic-level power-supply voltage.

- Notes on display-off mode (LCDC stopped)

If LCD module power-supply control-sequence processing is in use by the LCDC or the supply of power is cut off while the LCDC is in its display-on mode, normal operation is not guaranteed. In the worst case, the connected LCD module may be damaged.

#### 24.4.7 Operation for Hardware Rotation

Operation in hardware-rotation mode is described below. Hardware-rotation mode can be thought of as using a landscape-format LCD panel instead of a portrait-format LCD panel by placing the landscape-format LCD panel as if it were a portrait-format panel. Whether the panel is intended for use in landscape or portrait format is thus no problem. The panel must, however, be within 320 pixels wide.

When making settings for hardware rotation, the following five differences from the setting for no hardware rotation must be noted. (The following example is for a display at 8 bpp. At 16 bpp, the amount of memory per dot will be doubled. The image size and register values used for rotation will thus be different.)

1. The image data must be prepared for display in the rotated panel. (If  $240 \times 320$  pixels will be required after rotation,  $240 \times 320$  pixel image data must be prepared.)
2. The register settings for the address of the image data must be changed (LDSARU and LDLAOR).
3. LDLAOR should be power of 2 (when the horizontal width after rotation is 240 pixels, LDLAOR should be set to 256).
4. Graphics software should be set up for the number 3 setting.
5. LDSARU should be changed to represent the address of the data for the lower-left pixel of the image rather than of the data for the upper-left pixel of the image.

**Figure 24.9 Operation for Hardware Rotation (Normal Mode)**

For example, the registers have been set up for the display of image data in landscape format ( $320 \times 240$ ), which starts from  $\text{LDSARU} = 0x0c001000$ , on a  $320 \times 240$  LCD panel. The graphics driver software is complete. Some changes are required to apply hardware rotation and use the panel as a  $240 \times 320$  display. If LDLAOR is 512, the graphics driver software uses this power of 2 as the offset for the calculation of the addresses of Y coordinates in the image data. Before setting ROT to 1, the image data must be redrawn to suit the  $240 \times 320$  LCD panel. LDLAOR will then

be 256 because the size has changed and the graphics driver software must be altered accordingly. The point that corresponds to LDSARU moves from the upper left to the lower left of the display, so LDSARU should be changed to  $0x0c001000 + 256 * 319$ .

**Note:** Hardware rotation allows the use of an LCD panel that has been rotated by 90 degrees. The settings in relation to the LCD panel should match the settings for the LCD panel before rotation. Rotation is possible regardless of the drawing processing carried out by the graphics driver software. However, the sizes in the image data and address offset values which are managed by the graphics driver software must be altered.

## 24.6 Usage Notes

### 24.6.1 Procedure for Halting Access to Display Data Storage VRAM (Synchronous DRAM in Area 3)

Follow the procedure below to halt access to VRAM for storing display data (synchronous DRAM in area 3).

- Procedure for Halting Access to Display Data Storage VRAM:
  1. Confirm that the LPS1 and LPS0 bits in LDPMMR are currently set to 1.
  2. Clear the DON bit in LDCNTR to 0 (display-off mode).
  3. Confirm that the LPS1 and LPS0 bits in LDPMMR have changed to 0.
  4. Wait for the display time for a single frame to elapse.

This halting procedure is required before selecting self-refreshing for the display data storage VRAM (synchronous DRAM in area 3) or making a transition to standby mode or module standby mode.

## Section 25 Pin Function Controller (PFC)

The pin function controller (PFC) is composed of registers that are used to select the functions of multiplexed pins and assign pins to be inputs or outputs. Tables 25.1 to 25.6 list the multiplexed pins of this LSI.

**Table 25.1 Multiplexed Pins (Port A)**

| Port | Function 1<br>(Related Module) | Function 2<br>(Related Module) | Function 3<br>(Related Module) |
|------|--------------------------------|--------------------------------|--------------------------------|
| A    | PA7 input (port)               | AN7 input (ADC)                | DA1 output (DAC)               |
|      | PA6 input (port)               | AN6 input (ADC)                | DA0 output (DAC)               |
|      | PA5 input (port)               | AN5 input (ADC)                | —                              |
|      | PA4 input (port)               | AN4 input (ADC)                | —                              |
|      | PA3 input (port)               | AN3 input (ADC)                | —                              |
|      | PA2 input (port)               | AN2 input (ADC)                | —                              |
|      | PA1 input (port)               | AN1 input (ADC)                | —                              |
|      | PA0 input (port)               | AN0 input (ADC)                | —                              |

## 25.1 Features

- By setting the control registers, multiplexed pin functions can be selectable.
- When the general I/O function or TIOC I/O function of MTU2 is specified, the I/O direction can be selected by I/O register settings.
- Switching the port A function by the settings of the A/D control/status register of the A/D converter (ADCSR) or D/A control register of the D/A converter (DACR).

## 25.2 Register Descriptions

The PFC has the following registers.

**Table 25.7 Register Configuration**

| Register Name                    | Abbreviation | R/W | Initial Value                   | Address    | Access Size              |
|----------------------------------|--------------|-----|---------------------------------|------------|--------------------------|
| Port B I/O register L            | PBIORL       | R/W | H'0000                          | H'FFFE3886 | 8, 16                    |
| Port B control register L4       | PBCRL4       | R/W | H'0001                          | H'FFFE3890 | 8 <sup>*1</sup> , 16, 32 |
| Port B control register L3       | PBCRL3       | R/W | H'0000                          | H'FFFE3892 | 8, 16                    |
| Port B control register L2       | PBCRL2       | R/W | H'0000                          | H'FFFE3894 | 8, 16, 32                |
| Port B control register L1       | PBCRL1       | R/W | H'0000                          | H'FFFE3896 | 8, 16                    |
| IRQOUT function control register | IFCR         | R/W | H'0000                          | H'FFFE38A2 | 8, 16                    |
| Port C I/O register L            | PCIORL       | R/W | H'0000                          | H'FFFE3906 | 8, 16                    |
| Port C control register L4       | PCCRL4       | R/W | H'0000                          | H'FFFE3910 | 8, 16, 32                |
| Port C control register L3       | PCCRL3       | R/W | H'0000                          | H'FFFE3912 | 8, 16                    |
| Port C control register L2       | PCCRL2       | R/W | H'0000                          | H'FFFE3914 | 8, 16, 32                |
| Port C control register L1       | PCCRL1       | R/W | H'0000/<br>H'0010 <sup>*2</sup> | H'FFFE3916 | 8, 16                    |
| Port D I/O register L            | PDIORL       | R/W | H'0000                          | H'FFFE3986 | 8, 16                    |
| Port D control register L4       | PDCRL4       | R/W | H'0000/<br>H'1111 <sup>*2</sup> | H'FFFE3990 | 8, 16, 32                |
| Port D control register L3       | PDCRL3       | R/W | H'0000/<br>H'1111 <sup>*2</sup> | H'FFFE3992 | 8, 16                    |
| Port D control register L2       | PDCRL2       | R/W | H'0000/<br>H'1111 <sup>*2</sup> | H'FFFE3994 | 8, 16, 32                |
| Port D control register L1       | PDCRL1       | R/W | H'0000/<br>H'1111 <sup>*2</sup> | H'FFFE3996 | 8, 16                    |
| Port E I/O register L            | PEIORL       | R/W | H'0000                          | H'FFFE3A06 | 8, 16                    |
| Port E control register L4       | PECRL4       | R/W | H'0000                          | H'FFFE3A10 | 8, 16, 32                |
| Port E control register L3       | PECRL3       | R/W | H'0000                          | H'FFFE3A12 | 8, 16                    |
| Port E control register L2       | PECRL2       | R/W | H'0000                          | H'FFFE3A14 | 8, 16, 32                |
| Port E control register L1       | PECRL1       | R/W | H'0000                          | H'FFFE3A16 | 8, 16                    |
| Port F I/O register H            | PFIORH       | R/W | H'0000                          | H'FFFE3A84 | 8, 16, 32                |
| Port F I/O register L            | PFIORL       | R/W | H'0000                          | H'FFFE3A86 | 8, 16                    |

| Register Name                             | Abbreviation | R/W | Initial Value | Address    | Access Size |
|-------------------------------------------|--------------|-----|---------------|------------|-------------|
| Port F control register H4                | PFCRH4       | R/W | H'0000        | H'FFFE3A88 | 8, 16, 32   |
| Port F control register H3                | PFCRH3       | R/W | H'0000        | H'FFFE3A8A | 8, 16       |
| Port F control register H2                | PFCRH2       | R/W | H'0000        | H'FFFE3A8C | 8, 16, 32   |
| Port F control register H1                | PFCRH1       | R/W | H'0000        | H'FFFE3A8E | 8, 16       |
| Port F control register L4                | PFCRL4       | R/W | H'0000        | H'FFFE3A90 | 8, 16, 32   |
| Port F control register L3                | PFCRL3       | R/W | H'0000        | H'FFFE3A92 | 8, 16       |
| Port F control register L2                | PFCRL2       | R/W | H'0000        | H'FFFE3A94 | 8, 16, 32   |
| Port F control register L1                | PFCRL1       | R/W | H'0000        | H'FFFE3A96 | 8, 16       |
| SSI oversampling clock selection register | SCSR         | R/W | H'0000        | H'FFFE3AA2 | 8, 16       |

Notes: 1. In 8-bit access, the register can be read but cannot be written to.  
 2. The initial value depends on the operating mode of the LSI.

### 25.2.1 Port B I/O Register L (PBIORL)

PBIORL is a 16-bit readable/writable register that is used to set the pins on port B as inputs or outputs. The PB11IOR to PB8IOR bits correspond to the PB11/CTx1 to PB8/CRx0/ CRx0/CRx1 pins, respectively. PBIORL is enabled when the port B pins are functioning as general-purpose input/output (PB11 to PB18). In other states, they are disabled. If a bit in PBIORL is set to 1, the corresponding pin on port B functions as output. If it is cleared to 0, the corresponding pin functions as input.

Bits 15 to 12 and bits 7 to 0 in PBIORL are reserved. These bits are always read as 0. The write value should always be 0.

## 25.2.2 Port B Control Registers L1 to L4 (PBCRL1 to PBCRL4)

PBCRL1 to PBCRL4 are 16-bit readable/writable registers that are used to select the function of the multiplexed pins on port B.

### (1) Port B Control Register L4 (PBCRL4)

|                |    |    |    |    |    |    |   |   |   |   |   |   |   |   |             |     |
|----------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|-------------|-----|

Note: Data must be written by 16/32-bit access setting H'5A in bits 15 to 8.  
Writing by 8-bit access is disabled.

### 25.2.3 Port C I/O Register L (PCIORL)

PCIORL is a 16-bit readable/writable register that is used to set the pins on port C as inputs or outputs. The PC14IOR to PC0IOR bits correspond to the PC14/ $\overline{\text{WAIT}}$  to PC0/A0/ $\overline{\text{CS}}$ 7 pins, respectively. PCIORL is enabled when the port C pins are functioning as general-purpose inputs/outputs (PC14 to PC0). In other states, PCIORL is disabled. If a bit in PCIORL is set to 1, the corresponding pin on port C functions as an output pin. If it is cleared to 0, the corresponding pin functions as an input pin.

Bit 15 of PCIORL is reserved. This bit is always read as 0. The write value should always be 0.

### 25.2.4 Port C Control Register L1 to L4 (PCCRL1 to PCCRL4)

PCCRL1 to PCCRL4 are 16-bit readable/writable registers that are used to select the functions of the multiplexed pins on port C.

#### (1) Port C Control Register L4 (PCCRL4)

|                |    |    |    |    |    |    |   |          |   |   |   |          |   |   |   |          |
|----------------|----|----|----|----|----|----|---|----------|---|---|---|----------|---|---|---|----------|

### 25.2.5 Port D I/O Register L (PDIORL)

PDIORL is a 16-bit readable/writable register that is used to set the pins on port D as inputs or outputs. The PD15IOR to PD0IOR bits correspond to the PD15/D31/PINT7/ $\overline{\text{ADTRG}}$ /TIOC4D to PD0/D16/IRQ0/SSCK0/DREQ2/TIOC0A pins, respectively. PDIORL is enabled when the port D pins are functioning as general-purpose inputs/outputs (PD15 to PD0) or the TIOC pin is functioning as inputs/outputs of MTU2. In other states, PDIORL is disabled. If a bit in PDIORL is set to 1, the corresponding pin on port D functions as an output. If it is cleared to 0, the corresponding pin functions as an input.

## 25.2.6 Port D Control Registers L1 to L4 (PDCRL1 to PDCRL4)

PDCRL1 to PDCRL4 are 16-bit readable/writable registers that are used to select the functions of the multiplexed pins on port D.

### (1) Port D Control Register L4 (PDCRL4)

Note: \* The initial value depends on the operating mode of the LSI.

## 25.2.7 Port E I/O Register L (PEIORL)

PEIORL is 16-bit readable/writable register that is used to set the pins on port E as inputs or outputs. The PE15IOR to PE0IOR bits correspond to the PE15/IOIS16/RTS3 to PE0/BS/RxD0/ADTRG pins respectively. PEIORL is enabled when the port E pins are functioning as general-purpose inputs/outputs (PE15 to PE0). In other states, it is disabled. If a bit in PEIORL is set to 1, the corresponding pin on port E functions as an output pin. If it is cleared to 0, the corresponding pin functions as an input pin.

## 25.2.8 Port E Control Registers L1 to L4 (PECRL1 to PECRL4)

PECRL1 to PECRL4 are 16-bit readable/writable registers that are used to select the functions of the multiplexed pins on port E.

### 25.2.9 Port F I/O Registers H, L (PFIORH, PFIORL)

PFIORH and PFIORL are 16-bit readable/writable registers that are used to set the pins on port F as inputs or outputs. The PF30IOR to PF0IOR bits correspond to the PF30/AUDIO\_CLK to PF0/TCLKA/LCD\_DATA0/SSCK0 pins, respectively. PFIORH and PFIORL are enabled when the port F pins are functioning as general-purpose inputs/outputs (PF30 to PF0). In other states, they are disabled. If a bit in PFIORH/PFIORL is set to 1, the corresponding pin on port F functions as an output. If it is cleared to 0, the corresponding pin functions as an input.

Bit 15 of PFIORH is reserved. This bit is always read as 0. The write value should always be 0.

### 25.2.11 IRQOUT Function Control Register (IFCR)

IFCR is a 16-bit readable/writable register that is used to control the  $\overline{\text{IRQOUT}}/\overline{\text{REFOUT}}$  pin output when it is selected as the multiplexed pin function by port B control register L4 (PBCRL4). When PBCRL4 selects another function, the IFCR setting does not affect the pin function.

| 111                                       | EXTAL input/8                    | CKIO input/8 | Setting prohibited |

Notes: 1. n = 0 to 3

2. When using the AUDIO\_CLK input clock, set the PF30MD0 bit of the port F control register H4 (PFCRH4) to 1.

## 25.3 Switching Pin Function of Port A

In port A, the analog input pins of A/D converter and the analog output pins of D/A converter are multiplexed. Pin function is automatically changed by the settings of the A/D control/status register in A/D converter and D/A control register in D/A converter. (See section 20, A/D Converter (ADC), and section 21, D/A Converter (DAC).)

**Table 25.9 Switching Pin Function of PA6/AN6/DA0 and PA7/AN7/DA1**

| DACR Setting Value            | ADCSR Setting Value |        | Pin Function |             | Remarks            |
|-------------------------------|---------------------|--------|--------------|-------------|--------------------|

|                               | 111                 | 0      | DA0          | AN7/DA1     | Setting prohibited |
|                               |                     | 1      | AN6/DA0      | AN7/DA1     | Setting prohibited |

[Legend]

x: Don't care

Note: Settings marked "setting prohibited" are not allowed because they would result in simultaneous selection of the A/D and D/A conversion functions for the PA6 or PA7 pin.

## 25.4 Usage Notes

The multiplexed pins listed in tables 25.1 to 25.6 except pins PA0 to PA7 and PB0 to PB7 include weak keepers in their I/O buffers to prevent the pins from floating into intermediate voltage levels. However, note that the voltage retained in the high-impedance state may fluctuate due to noise.

## Section 26 I/O Ports

This LSI has six ports: A to F.

All port pins are multiplexed with other pin functions. The functions of the multiplex pins are selected by means of the pin function controller (PFC).

Each port is provided with data registers for storing the pin data and port registers for reading the states of the pins.

### 26.1 Features

1. Total port number: 99 ports (I/O: 82 ports, Input: 16 ports, Output: 1 ports)
  - Port A: (Input: 8 ports)
  - Port B: (I/O: 4 ports, Input: 8 ports, Output: 1 port)
  - Port C: (I/O: 15 ports)
  - Port D: (I/O: 16 ports)
  - Port E: (I/O: 16 ports)
  - Port F: (I/O: 31 ports)
2. The following pins in this LSI have weak keeper circuits that prevent the pins from floating into intermediate voltage levels.
  - Port B: PB8 to PB12
  - Port C: PC0 and PC14
  - Port D: PD0 to PD15
  - Port E: PE0 to PE15
  - Port F: PF0 to PF30

The I/O pins include weak keeper circuits that fix the input level high or low when the I/O pins are not driven from outside. Generally in the CMOS products, input levels in unused input pins must be fixed by way of external pull-up or pull-down resistors. However, the I/O pins having weak keeper circuits in this LSI can eliminate these outer circuits and reduce parts number of the system. If the pull-up or pull-down resistors become necessary to fix the pin level, use the resistor of 10 k $\Omega$  or smaller.

26.2 Port A

Port A is an input/output port with eight pins as shown in figure 26.1.

Figure 26.1 Port A

26.2.1 Register Descriptions

Table 26.1 lists the port A registers.

Table 26.1 Register Configuration

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port A data register L | PADRL        | R   | H'00xx        | H'FFFE3802 | 8, 16       |

26.2.2 Port A Data Register L (PADRL)

PADRL is a 16-bit read-only register that stores port A data. The PA7DR to PA0DR bits correspond to the PA7/AN7/DA1 to PA0/AN0 pins, respectively. The general input function of the PA7 to PA0 pins is enabled only when the A/D and D/A converters are halted.

Writing to these bits is ignored, and therefore does not affect the pin state. If these bits are read, the pin state, not the bit value, is directly returned. Note that, however, this register should not be read during operation of the A/D or D/A converter. Table 26.2 summarizes PADRL read/write operation.

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
|----------------|----|----|----|----|----|----|---|---|--------|--------|--------|--------|--------|--------|--------|--------|
|                | -  | -  | -  | -  | -  | -  | - | - | PA7 DR | PA6 DR | PA5 DR | PA4 DR | PA3 DR | PA2 DR | PA1 DR | PA0 DR |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | *      | *      | *      | *      | *      | *      | *      | *      |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R      | R      | R      | R      | R      | R      | R      | R      |

Note: \* Depends on the state of the external pin.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                      |
|---------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 15 to 8 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7       | PA7DR    | Pin state     | R   | See table 26.2.                                                                  |
| 6       | PA6DR    | Pin state     | R   |                                                                                  |
| 5       | PA5DR    | Pin state     | R   |                                                                                  |
| 4       | PA4DR    | Pin state     | R   |                                                                                  |
| 3       | PA3DR    | Pin state     | R   |                                                                                  |
| 2       | PA2DR    | Pin state     | R   |                                                                                  |
| 1       | PA1DR    | Pin state     | R   |                                                                                  |
| 0       | PA0DR    | Pin state     | R   |                                                                                  |

**Table 26.2 Port A Data Registers L (PADRL) Read/Write Operation**

- Bits 7 to 0 of PADRL

| Pin Function         | Read Operation | Write Operation                          |
|----------------------|----------------|------------------------------------------|
| General input        | Pin state      | Ignored (Does not affect the pin state.) |
| ANn input/DAn output | Disabled       | Ignored (Does not affect the pin state.) |

[Legend]

n = 7 to 0 (DA: DA0 and DA1 only)

## 26.3 Port B

Port B is an input/output port with thirteen pins as shown in figure 26.2.

Figure 26.2 Port B

### 26.3.1 Register Descriptions

Table 26.3 lists the port B registers.

Table 26.3 Register Configuration

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port B data register L | PBDRL        | R/W | H'00xx        | H'FFFE3882 | 8, 16       |
| Port B port register L | PBPRL        | R   | H'xxxx        | H'FFFE389E | 8, 16       |

## 26.3.2 Port B Data Register L (PBDRL)

PBDRL is a 16-bit readable/writable register that stores port B data. The PB12DR to PB0DR bits correspond to the PB12/WDTOVF/IRQOUT/REFOUT/UBCTR<sub>G</sub> to PB0/SCL0/PINT0/IRQ0 pins, respectively.

When a pin function is general output, if a value is written to PBDRL, that value is output directly from the pin, and if PBDRL is read, the register value is returned directly regardless of the pin state.

When a pin function is general input, if PBDRL is read, the pin state, not the register value, is returned directly. If a value is written to PBDRL, although that value is written into PBDRL, it does not affect the pin state. Table 26.4 summarizes PBDRL read/write operations.

|                |    |    |    |            |            |            |           |           |           |           |           |           |           |           |           |           |
|----------------|----|----|----|------------|------------|------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| Bit:           | 15 | 14 | 13 | 12         | 11         | 10         | 9         | 8         | 7         | 6         | 5         | 4         | 3         | 2         | 1         | 0         |
|                | -  | -  | -  | PB12<br>DR | PB11<br>DR | PB10<br>DR | PB9<br>DR | PB8<br>DR | PB7<br>DR | PB6<br>DR | PB5<br>DR | PB4<br>DR | PB3<br>DR | PB2<br>DR | PB1<br>DR | PB0<br>DR |
| Initial value: | 0  | 0  | 0  | 0          | 0          | 0          | 0         | 0         | *         | *         | *         | *         | *         | *         | *         | *         |
| R/W:           | R  | R  | R  | R/W        | R/W        | R/W        | R/W       | R/W       | R         | R         | R         | R         | R         | R         | R         | R         |

Note: \* Depends on the state of the external pin.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                      |
|----------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 15 to 13 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 12       | PB12DR   | 0             | R/W | See table 26.4.                                                                  |
| 11       | PB11DR   | 0             | R/W |                                                                                  |
| 10       | PB10DR   | 0             | R/W |                                                                                  |

| 2        | PB2DR    | Pin state     | R   |                                                                                  |
| 1        | PB1DR    | Pin state     | R   |                                                                                  |
| 0        | PB0DR    | Pin state     | R   |                                                                                  |

**Table 26.4 Port B Data Register L (PBDRL) Read/Write Operations**

- Bit 12 of PBDRL

| Pin Function              | Read Operation | Write Operation                                       |
|---------------------------|----------------|-------------------------------------------------------|
| General output            | PBDRL value    | Value written is output from pin                      |
| Other than general output | PBDRL value    | Can write to PBDRL, but it has no effect on pin state |

- Bits 11 to 8 of PBDRL

| PBIORL | Pin Function              | Read Operation | Write Operation                                       |
|--------|---------------------------|----------------|-------------------------------------------------------|
| 0      | General input             | Pin state      | Can write to PBDRL, but it has no effect on pin state |
|        | Other than general input  | Pin state      | Can write to PBDRL, but it has no effect on pin state |
| 1      | General output            | PBDRL value    | Value written is output from pin                      |
|        | Other than general output | PBDRL value    | Can write to PBDRL, but it has no effect on pin state |

- Bit 7 to 0 of PBDRL

| Pin Function             | Read Operation | Write Operation |
|--------------------------|----------------|-----------------|
| General input            | Pin state      | Disabled        |
| Other than general input | Pin state      | Disabled        |

### 26.3.3 Port B Port Register L (PBPRL)

PBPRL is a 16-bit read-only register, in which the PB11PR to PB0PR bits correspond to the PB11/CTx1 to PB0/SCL0/PINT0/IRQ0 pins, respectively. PBPRL always returns the states of the pins regardless of the PFC setting.

|                |    |    |    |    |            |            |           |           |           |           |           |           |           |           |           |           |
|----------------|----|----|----|----|------------|------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| Bit:           | 15 | 14 | 13 | 12 | 11         | 10         | 9         | 8         | 7         | 6         | 5         | 4         | 3         | 2         | 1         | 0         |

26.4 Port C

Port C is an input/output port with fifteen pins as shown in figure 26.3.

Figure 26.3 Port C

26.4.1 Register Descriptions

Table 26.5 lists the port C registers.

Table 26.5 Register Configuration

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port C data register L | PCDRL        | R/W | H'xxxx        | H'FFFE3902 | 8, 16       |
| Port C port register L | PCPRL        | R   | H'xxxx        | H'FFFE391E | 8, 16       |

## 26.4.2 Port C Data Register L (PCDRL)

PCDRL is a 16-bit readable/writable register that stores port C data. The PC14DR to PC0DR bits correspond to the PC14/WAIT to PC0/A0/CS7 pins, respectively.

When a pin function is general output, if a value is written to PCDRL, that value is output directly from the pin, and if PCDRL is read, the register value is returned directly regardless of the pin state.

When a pin function is general input, if PCDRL is read, the pin state, not the register value, is returned directly. If a value is written to PCDRL, although that value is written into PCDRL, it does not affect the pin state. Table 26.6 summarizes PCDRL read/write operations.

| 0   | PC0DR    | 0             | R/W |                                                                               |

**Table 26.6 Port C Data Register L (PCDRL) Read/Write Operations**

- Bits 14 to 0 of PCDRL

| PCIORL | Pin Function              | Read Operation | Write Operation                                       |
|--------|---------------------------|----------------|-------------------------------------------------------|
| 0      | General input             | Pin state      | Can write to PCDRL, but it has no effect on pin state |
|        | Other than general input  | Pin state      | Can write to PCDRL, but it has no effect on pin state |
| 1      | General output            | PCDRL value    | Value written is output from pin                      |
|        | Other than general output | PCDRL value    | Can write to PCDRL, but it has no effect on pin state |

### 26.4.3 Port C Port Register L (PCPRL)

PCPRL is a 16-bit read-only register, in which the PC14PR to PC0PR bits correspond to the PC14/WAIT to PC0/A0/CS7 pins, respectively. PCPRL always returns the states of the pins regardless of the PFC setting.

26.5 Port D

Port D is an input/output port with sixteen pins as shown in figure 26.4.

Figure 26.4 Port D

26.5.1 Register Descriptions

Table 26.7 lists the port D registers.

Table 26.7 Register Configuration

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port D data register L | PDDRL        | R/W | H'0000        | H'FFFE3982 | 8, 16       |
| Port D port register L | PDPRL        | R   | H'xxxx        | H'FFFE399E | 8, 16       |

## 26.5.2 Port D Data Registers L (PDDRL)

PDDRL is a 16-bit readable/writable register that stores port D data. The PD15DR to PD0DR bits correspond to the PD15/D31/PINT7/ADTRG/TIOC4D to PD0/D16/IRQ0/SSCK0/DREQ2/TIOC0A pins, respectively.

When a pin function is general output, if a value is written to PDDRL, that value is output directly from the pin, and if PDDRL is read, the register value is returned directly regardless of the pin state.

When a pin function is general input, if PDDRL is read, the pin state, not the register value, is returned directly. If a value is written to PDDRL, although that value is written into PDDRL, it does not affect the pin state. Table 26.8 summarizes PDDRL read/write operation.

| Bit:           | 15     | 14     | 13     | 12     | 11     | 10     | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|----------------|--------|--------|--------|--------|--------|--------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
|                | PD15DR | PD14DR | PD13DR | PD12DR | PD11DR | PD10DR | PD9DR | PD8DR | PD7DR | PD6DR | PD5DR | PD4DR | PD3DR | PD2DR | PD1DR | PD0DR |
| Initial value: | 0      | 0      | 0      | 0      | 0      | 0      | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |
| R/W:           | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |

| Bit | Bit Name | Initial Value | R/W | Description     |
|-----|----------|---------------|-----|-----------------|
| 15  | PD15DR   | 0             | R/W | See table 26.8. |
| 14  | PD14DR   | 0             | R/W |                 |
| 13  | PD13DR   | 0             | R/W |                 |
| 12  | PD12DR   | 0             | R/W |                 |
| 11  | PD11DR   | 0             | R/W |                 |
| 10  | PD10DR   | 0             | R/W |                 |
| 9   | PD9DR    | 0             | R/W |                 |
| 8   | PD8DR    | 0             | R/W |                 |
| 7   | PD7DR    | 0             | R/W |                 |
| 6   | PD6DR    | 0             | R/W |                 |
| 5   | PD5DR    | 0             | R/W |                 |
| 4   | PD4DR    | 0             | R/W |                 |
| 3   | PD3DR    | 0             | R/W |                 |
| 2   | PD2DR    | 0             | R/W |                 |
| 1   | PD1DR    | 0             | R/W |                 |
| 0   | PD0DR    | 0             | R/W |                 |

**Table 26.8 Port D Data Registers L (PDDRL) Read/Write Operation**

- Bits 15 to 0 of PDDRL

| PDIORL | Pin Function              | Read Operation | Write Operation                                       |
|--------|---------------------------|----------------|-------------------------------------------------------|
| 0      | General input             | Pin state      | Can write to PDDRL, but it has no effect on pin state |
|        | Other than general input  | Pin state      | Can write to PDDRL, but it has no effect on pin state |
| 1      | General output            | PDDRL value    | Value written is output from pin                      |
|        | Other than general output | PDDRL value    | Can write to PDDRL, but it has no effect on pin state |

### 26.5.3 Port D Port Registers L (PDPRL)

PDPRL is a 16-bit read-only register, in which the PD15PR to PD0PR bits correspond to the PD15/D31/PINT7/ADTRG/TIOC4D to PD0/D16/IRQ0/SSCK0/DREQ2/TIOC0A pins, respectively. PDPRL always returns the states of the pins regardless of the PFC setting.

|                |            |            |            |            |            |            |           |           |           |           |           |           |           |           |           |           |
|----------------|------------|------------|------------|------------|------------|------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| Bit:           | 15         | 14         | 13         | 12         | 11         | 10         | 9         | 8         | 7         | 6         | 5         | 4         | 3         | 2         | 1         | 0         |

26.6 Port E

Port E is an input/output port with sixteen pins as shown in figure 26.5.

Figure 26.5 Port E

26.6.1 Register Descriptions

Table 26.9 lists the port E registers.

Table 26.9 Register Configuration

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port E data register L | PEDRL        | R/W | H'0000        | H'FFFE3A02 | 8, 16       |
| Port E port register L | PEPRL        | R   | H'xxxx        | H'FFFE3A1E | 8, 16       |

## 26.6.2 Port E Data Registers L (PEDRL)

PEDRL is a 16-bit readable/writable register that stores port E data. The PE15DR to PE0DR bits correspond to the PE15/ $\overline{\text{IOIS16}}$ /RTS3 to PE0/BS/RxD0/ADTRG pins, respectively.

When a pin function is general output, if a value is written to PEDRL, that value is output directly from the pin, and if PEDRL is read, the register value is returned directly regardless of the pin state.

When a pin function is general input, if PEDRL is read, the pin state, not the register value, is returned directly. If a value is written to PEDRL, although that value is written into PEDRL, it does not affect the pin state. Table 26.10 summarizes PEDRL read/write operation.

|                |            |            |            |            |            |            |           |           |           |           |           |           |           |           |           |           |
|----------------|------------|------------|------------|------------|------------|------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| Bit:           | 15         | 14         | 13         | 12         | 11         | 10         | 9         | 8         | 7         | 6         | 5         | 4         | 3         | 2         | 1         | 0         |
|                | PE15<br>DR | PE14<br>DR | PE13<br>DR | PE12<br>DR | PE11<br>DR | PE10<br>DR | PE9<br>DR | PE8<br>DR | PE7<br>DR | PE6<br>DR | PE5<br>DR | PE4<br>DR | PE3<br>DR | PE2<br>DR | PE1<br>DR | PE0<br>DR |

| 4   | PE4DR    | 0             | R/W |                  |
| 3   | PE3DR    | 0             | R/W |                  |
| 2   | PE2DR    | 0             | R/W |                  |
| 1   | PE1DR    | 0             | R/W |                  |
| 0   | PE0DR    | 0             | R/W |                  |

**Table 26.10 Port E Data Registers L (PEDRL) Read/Write Operation**

- Bits 15 to 0 of PEDRL

| PEIORL | Pin Function              | Read Operation | Write Operation                                       |
|--------|---------------------------|----------------|-------------------------------------------------------|
| 0      | General input             | Pin state      | Can write to PEDRL, but it has no effect on pin state |
|        | Other than general input  | Pin state      | Can write to PEDRL, but it has no effect on pin state |
| 1      | General output            | PEDRL value    | Value written is output from pin                      |
|        | Other than general output | PEDRL value    | Can write to PEDRL, but it has no effect on pin state |

### 26.6.3 Port E Port Registers L (PEPRL)

PEPRL is a 16-bit read-only register, in which the PE15PR to PE0PR bits correspond to the PE15/ $\overline{\text{IOIS16}}$ /RTS3 to PE0/BS/RxD0/ADTRG pins, respectively. PEPRL always returns the states of the pins regardless of the PFC setting.

## 26.7 Port F

Port F is an input/output port with thirty-one pins as shown in figure 26.6.

**Figure 26.6 Port F**

## 26.7.1 Register Descriptions

Table 26.11 lists the port F register.

**Table 26.11 Register Configuration**

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port F data register H | PFDRH        | R/W | H'0000        | H'FFFE3A80 | 8, 16, 32   |
| Port F data register L | PFDRL        | R/W | H'0000        | H'FFFE3A82 | 8, 16       |
| Port F port register H | PFPRH        | R   | H'xxxx        | H'FFFE3A9C | 8, 16, 32   |
| Port F port register L | PFPRL        | R   | H'xxxx        | H'FFFE3A9E | 8, 16       |

## 26.7.2 Port F Data Registers H and L (PFDRH, PFDRL)

PFDRH and PFDRL are 16-bit readable/writable registers that store port F data. The PF30DR to PF0DR bits correspond to the PF30/AUDIO\_CLK to PF0/TCLKA/LCD\_DATA0/SSCK0 pins, respectively.

When a pin function is general output, if a value is written to PEDRH or PEDRL, that value is output directly from the pin, and if PEDRH or PEDRL is read, the register value is returned directly regardless of the pin state.

When a pin function is general input, if PEDRH or PEDRL is read, the pin state, not the register value, is returned directly. If a value is written to PEDRH or PEDRL, although that value is written into PEDRH or PEDRL, it does not affect the pin state. Table 26.12 summarizes PFDRH/PFDRL read/write operation.

| 4   | PF4DR    | 0             | R/W |                  |
| 3   | PF3DR    | 0             | R/W |                  |
| 2   | PF2DR    | 0             | R/W |                  |
| 1   | PF1DR    | 0             | R/W |                  |
| 0   | PF0DR    | 0             | R/W |                  |

**Table 26.12 Read/Write Operations of Port F Data Registers H and L (PFDRH, PFDRL)**

- Bits 14 to 0 of PFDRH and bits 15 to 0 of PFDRL

| <b>PFIORH,<br/>PFIORL</b> | <b>Pin Function</b>       | <b>Read Operation</b> | <b>Write Operation</b>                                      |
|---------------------------|---------------------------|-----------------------|-------------------------------------------------------------|
| 0                         | General input             | Pin state             | Can write to PFDRH/PFDRL, but it has no effect on pin state |
|                           | Other than general input  | Pin state             | Can write to PFDRH/PFDRL, but it has no effect on pin state |
| 1                         | General output            | PFDRH/PFDRL value     | Value written is output from pin                            |
|                           | Other than general output | PFDRH/PFDRL value     | Can write to PFDRH/PFDRL, but it has no effect on pin state |

## 26.7.3 Port F Port Registers H and L (PFPRH, PFPRL)

PFPRH and PFPRL are 16-bit read-only registers, in which the PF30PR to PF0PR bits correspond to the PF30/AUDIO\_CLK to PF0/TCLKA/LCD\_DATA0/SSCK0 pins, respectively. PFPRH and PFPRL always return the states of the pins regardless of the PFC setting.

### (1) Port F Port Register H (PFPRH)

|                |    |            |            |            |            |            |            |            |            |            |            |            |            |            |            |            |
|----------------|----|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|
| Bit:           | 15 | 14         | 13         | 12         | 11         | 10         | 9          | 8          | 7          | 6          | 5          | 4          | 3          | 2          | 1          | 0          |
|                | -  | PF30<br>PR | PF29<br>PR | PF28<br>PR | PF27<br>PR | PF26<br>PR | PF25<br>PR | PF24<br>PR | PF23<br>PR | PF22<br>PR | PF21<br>PR | PF20<br>PR | PF19<br>PR | PF18<br>PR | PF17<br>PR | PF16<br>PR |
| Initial value: | 0  | *          | *          | *          | *          | *          | *          | *          | *          | *          | *          | *          | *          | *          | *          | *          |
| R/W:           | R  | R          | R          | R          | R          | R          | R          | R          | R          | R          | R          | R          | R          | R          | R          | R          |

Note: \* Depends on the state of the external pin.

| Bit | Bit Name | Initial Value | R/W | Description                                                                             |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------|
| 15  | —        | 0             | R   | Reserved<br>This bit is always read as 0. The write value should always be 0.           |
| 14  | PF30PR   | Pin state     | R   | The pin state is returned regardless of the PFC setting. These bits cannot be modified. |
| 13  | PF29PR   | Pin state     | R   |                                                                                         |
| 12  | PF28PR   | Pin state     | R   |                                                                                         |
| 11  | PF27PR   | Pin state     | R   |                                                                                         |

| 5   | PF5PR    | Pin state     | R   |                                                                                         |
| 4   | PF4PR    | Pin state     | R   |                                                                                         |
| 3   | PF3PR    | Pin state     | R   |                                                                                         |
| 2   | PF2PR    | Pin state     | R   |                                                                                         |
| 1   | PF1PR    | Pin state     | R   |                                                                                         |
| 0   | PF0PR    | Pin state     | R   |                                                                                         |

## 26.8 Usage Notes

When the PFC selects the following pin functions, the pin state cannot be read by accessing data registers or port registers.

- A25 to A21, A1, and A0 (address bus)
- D31 to D16 (data bus)
- $\overline{\text{BS}}$
- $\overline{\text{CS7}}$ ,  $\overline{\text{CS4}}$  to  $\overline{\text{CS1}}$ ,  $\overline{\text{CS5/CE1A}}$ ,  $\overline{\text{CS6/CE1B}}$ ,  $\overline{\text{CE2A}}$ , and  $\overline{\text{CE2B}}$
- $\overline{\text{RD/WR}}$
- $\overline{\text{WE3/DQMUU/AH/ICIOWR}}$ ,  $\overline{\text{WE2/DQMUL/ICIO RD}}$ ,  $\overline{\text{WE1/DQMLU/WE}}$ , and  $\overline{\text{WE0/DQMLL}}$
- $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASU}}$ , and  $\overline{\text{CASL}}$
- $\overline{\text{CKE}}$
- $\overline{\text{FRAME}}$
- $\overline{\text{WAIT}}$
- $\overline{\text{BREQ}}$
- $\overline{\text{BACK}}$
- $\overline{\text{IOIS16}}$
- $\overline{\text{MRES}}$
- NAF7 to NAF0

## Section 27 On-Chip RAM

This LSI has an on-chip high-speed RAM, which achieves fast access, and an on-chip RAM for data retention, which can retain data in deep standby mode. These memory units can be used to store instructions or data.

On-chip high-speed RAM operation and write access to the RAM can be enabled or disabled through the RAM enable bits and RAM write enable bits.

Retention or non-retention of data by the on-chip RAM for data retention in deep standby mode is selectable on a per-page basis.

### 27.1 Features

- Memory map

The on-chip RAM is located in the address spaces shown in tables 27.1 and 27.2.

**Table 27.1 Address Spaces of On-Chip High-Speed RAM**

| Page   | Address                  |
|--------|--------------------------|
| Page 0 | H'FFF80000 to H'FFF83FFF |
| Page 1 | H'FFF84000 to H'FFF87FFF |
| Page 2 | H'FFF88000 to H'FFF8BFFF |
| Page 3 | H'FFF8C000 to H'FFF8FFFF |

**Table 27.2 Address Spaces of On-Chip RAM for Data Retention**

| Page   | Address                  |
|--------|--------------------------|
| Page 0 | H'FFFF8000 to H'FFFF8FFF |
| Page 1 | H'FFFF9000 to H'FFFF9FFF |
| Page 2 | H'FFFFA000 to H'FFFFAFFF |
| Page 3 | H'FFFFB000 to H'FFFFBFFF |

- Ports

Each page of the on-chip high-speed RAM has two independent read and write ports and is connected to the internal DMA bus (ID bus), CPU instruction fetch bus (F bus), and CPU memory access bus (M bus). (Note that the F bus is connected only to the read ports.)

The F bus and M bus are used for access by the CPU, and the ID bus is used for access by the DMAC.

The on-chip RAM for data retention has one read/write port and is connected to the peripheral bus.

- Priority

When the same page of the on-chip high-speed RAM is accessed from different buses simultaneously, the access is processed according to the priority. The priority is ID bus > M bus > F bus.

- Number of access cycles

On-chip high-speed RAM: the number of cycles for access to read or write from buses F and I is one cycle of  $I\phi$ . Number of cycles for access from the ID bus depend on the ratio of the internal clock ( $I\phi$ ) to the bus clock ( $B\phi$ ). Table 27.3 indicates number of cycles for access from the ID bus.

**Table 27.3 Number of Cycles for Access to On-Chip High-Speed RAM from the ID Bus**

| Read/Write | Ratio of $I\phi$ and $B\phi$ | Number of Access ( $B\phi$ ) Cycles |
|------------|------------------------------|-------------------------------------|
| Read       | 1:1                          | 3                                   |
|            | 1:2                          | 2                                   |
|            | 1:3                          | 2                                   |
|            | 1:4                          | 2                                   |
|            | 1:6                          | 1                                   |
|            | 1:8                          | 1                                   |
| Write      | 1:1                          | 2                                   |
|            | 1:2                          | 2                                   |
|            | 1:3                          | 2                                   |
|            | 1:4                          | 2                                   |
|            | 1:6                          | 1                                   |
|            | 1:8                          | 1                                   |

Note: For the settable ratios of  $I\phi$  to  $B\phi$ , see section 5, Clock Pulse Generator.

On-chip data retention RAM: The number of cycles required to read or write from the IC bus or ID bus ranges from 1  $B\phi$  + 2  $P\phi$  (minimum) to 3  $P\phi$  (maximum).

## 27.2 Usage Notes

### 27.2.1 Page Conflict

When the same page of the on-chip high-speed RAM is accessed from different buses simultaneously, a conflict on the page occurs. Although each access is completed correctly, this kind of conflict degrades the memory access speed. Therefore, it is advisable to provide software measures to prevent such conflicts as far as possible. For example, no conflict will arise if different pages are accessed by each bus.

### 27.2.2 RAME and RAMWE Bits

Before disabling memory operation or write access to the on-chip high-speed RAM through the RAME or RAMWE bit, be sure to read from any address and then write to the same address in each page; otherwise, the last written data in each page may not be actually written to the RAM.

```
// For page 0
MOV.L  #H'FFF80000,R0
MOV.L  @R0,R1
MOV.L  R1,@R0

// For page 1
MOV.L  #H'FFF84000,R0
MOV.L  @R0,R1
MOV.L  R1,@R0

// For page 2
MOV.L  #H'FFF88000,R0
MOV.L  @R0,R1
MOV.L  R1,@R0

// For page 3
MOV.L  #H'FFF8C000,R0
MOV.L  @R0,R1
MOV.L  R1,@R0
```

**Figure 27.1 Examples of Read/Write**

### 27.2.3 Areas where Placing Instructions Is Prohibited

Do not place instructions at the addresses within 16 bytes of the last address in the on-chip RAM for data retention, i.e., at addresses H'FFFFBFF0 to H'FFFFBFFF. If an instruction is placed at any of these prohibited locations, an overrun may cause the CPU to fetch from the address space (H'FFFFC000 and subsequent addresses) for the on-chip peripheral modules, and this will lead to an address error.

### 27.2.4 Data Retention

Data in the on-chip high-speed RAM and including on-chip data retention RAM are retained in the states other than power-on reset and deep standby mode. In power-on reset and deep standby mode, these RAMs operate as described below.

#### (1) Power-on Reset

##### (a) On-Chip High-Speed RAM

Data are retained on a power-on reset by disabling the setting of either the RAME or RAMWE bit.

Data are not retained when the setting of the RAME and RAMWE bits are both enabled.

##### (b) On-Chip Data Retention RAM

Data are not retained.

#### (2) Deep Standby Mode

##### (a) On-Chip High-Speed RAM

Data are not retained.

##### (b) On-Chip Data Retention RAM

Data are retained in deep standby mode by enabling the setting of the RRAMKP bit, excluding the case that deep standby mode is canceled by power-on reset. In the case that deep standby mode is canceled by interrupt or manual reset pins, power-on reset exception handling is executed, but the data are retained.

## Section 28 Power-Down Modes

This LSI supports sleep mode, software standby mode, deep standby mode, and module standby mode. In power-down modes, functions of CPU, clocks, on-chip memory, or part of on-chip peripheral modules are halted or the power-supply is turned off, through which low power consumption is achieved. These modes are canceled by a reset or interrupt.

### 28.1 Features

#### 28.1.1 Power-Down Modes

This LSI has the following power-down modes and function:

1. Sleep mode
2. Software standby mode
3. Deep standby mode
4. Module standby function

Table 28.1 shows the transition conditions for entering the modes from the program execution state, as well as the CPU and peripheral module states in each mode and the procedures for canceling each mode.

**Table 28.1 States of Power-Down Modes**

| State*1               |                                                                             |         |        |              |                                      |                                  |                            |           |              |                 |                                                                                                                                         |

|---------------------|--------------------------------------------|---------|---------|--------------|--------------------------------------|----------------------------------|----------------------------|--------|--------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------|
| Power-Down Mode     | Transition Conditions                      | CPG     | CPU     | CPU Register | On-Chip RAM (High-Speed) Cash Memory | On-Chip RAM (for Data Retention) | On-Chip Peripheral Modules | RTC    | Power supply | External Memory | Canceled Procedure                                                                                                               |
| Module standby mode | Set the MSTP bits in STBCR2 to STBCR6 to 1 | Running | Running | Held         | Running                              | Running                          | Specified module halted    | Halted | Running      | Auto-refresh    | <ul style="list-style-type: none"> <li>• Clear MSTP bit to 0</li> <li>• Power-on reset (only for H-UDI, UBC and DMAC)</li> </ul> |

- Notes:
1. The pin state is retained or set to high impedance. For details, see appendix A, Pin States.
  2. RTC operates when the START bit in the RCR2 register is set to 1. For details, see section 14, Realtime Clock (RTC). When deep standby mode is canceled by a power-on reset, the running state cannot be retained. Make the initial setting for the realtime clock again.
  3. Setting the bits RAMKP3 to RAMKP0 in the RAMKP register to 1 enables to retain the data in the corresponding area on the on-chip RAM during the transition to deep standby. However, the stored contents are initialized when deep standby mode is canceled by a power-on reset.
  4. Deep standby mode can be canceled by an interrupt (NMI or IRQ) or a reset (manual reset or power-on reset). However, when deep standby mode is canceled by the NMI interrupt or IRQ interrupt, power-on reset exception handling is executed instead of interrupt exception handling. The power-on reset exception handling is executed also in the cancellation of deep standby mode by manual reset.
  5. The stored contents are initialized when software standby mode is canceled by a power-on reset.
  6. The stored contents can be retained even when software standby mode is canceled by a power-on reset by disabling access to the on-chip RAM (high-speed) by means of the RAME bits in the SYSCR1 register or the RAMWE bits in the SYSCR2 register.

## 28.2 Register Descriptions

The following registers are used in power-down modes.

**Table 28.2 Register Configuration**

| Register Name                              | Abbreviation | R/W | Initial Value | Address    | Access Size |
|--------------------------------------------|--------------|-----|---------------|------------|-------------|
| Standby control register                   | STBCR        | R/W | H'00          | H'FFFE0014 | 8           |
| Standby control register 2                 | STBCR2       | R/W | H'00          | H'FFFE0018 | 8           |
| Standby control register 3                 | STBCR3       | R/W | H'7E          | H'FFFE0408 | 8           |
| Standby control register 4                 | STBCR4       | R/W | H'FF          | H'FFFE040C | 8           |
| Standby control register 5                 | STBCR5       | R/W | H'FF          | H'FFFE0410 | 8           |
| Standby control register 6                 | STBCR6       | R/W | H'FF          | H'FFFE0414 | 8           |
| System control register 1                  | SYSCR1       | R/W | H'FF          | H'FFFE0402 | 8           |
| System control register 2                  | SYSCR2       | R/W | H'FF          | H'FFFE0404 | 8           |
| System control register 3                  | SYSCR3       | R/W | H'00          | H'FFFE0418 | 8           |
| Deep standby control register              | DSCTR        | R/W | H'00          | H'FFFF2800 | 8           |
| Deep standby control register 2            | DSCTR2       | R/W | H'00          | H'FFFF2802 | 8           |
| Deep standby cancel source select register | DSSSR        | R/W | H'0000        | H'FFFF2804 | 16          |
| Deep standby cancel source flag register   | DSFR         | R/W | H'0000        | H'FFFF2808 | 16          |
| Retention on-chip RAM trimming register    | DSRTR        | R/W | H'00          | H'FFFF280C | 8           |

### 28.2.1 Standby Control Register (STBCR)

STBCR is an 8-bit readable/writable register that specifies the state of the power-down mode. Only byte access is valid.

Note: When writing to this register, see section 28.4, Usage Notes.

|                |      |      |   |   |   |   |   |   |
|----------------|------|------|---|---|---|---|---|---|
| Bit:           | 7    | 6    | 5 | 4 | 3 | 2 | 1 | 0 |

### 28.2.3 Standby Control Register 3 (STBCR3)

STBCR3 is an 8-bit readable/writable register that controls the operation of modules. Only byte access is valid.

Note: When writing to this register, see section 28.4, Usage Notes.

|                |     |   |            |   |   |            |            |            |

## 28.2.6 Standby Control Register 6 (STBCR6)

STBCR6 is an 8-bit readable/writable register that controls the operation of each module. Only byte access is valid.

Note: When writing to this register, see section 28.4, Usage Notes.

|                |            |            |            |            |   |   |   |            |

### 28.2.7 System Control Register 1 (SYSCR1)

SYSCR1 is an 8-bit readable/writable register that enables or disables access to the on-chip RAM (high-speed). Only byte access is valid.

When an RAME bit is set to 1, the corresponding on-chip RAM (high-speed) area is enabled. When an RAME bit is cleared to 0, the corresponding on-chip RAM (high-speed) area cannot be accessed. In this case, an undefined value is returned when reading data or fetching an instruction from the on-chip RAM (high-speed), and writing to the on-chip RAM (high-speed) is ignored. The initial value of an RAME bit is 1.

Note that when clearing the RAME bit to 0 to disable the on-chip RAM (high-speed), be sure to execute an instruction to read from or write to the same arbitrary address in each page before setting the RAME bit. If such an instruction is not executed, the data last written to each page may not be written to the on-chip RAM (high-speed). Furthermore, an instruction to access the on-chip RAM (high-speed) should not be located immediately after the instruction to write to SYSCR1. If an on-chip RAM (high-speed) access instruction is set, normal access is not guaranteed.

When setting the RAME bit to 1 to enable the on-chip RAM (high-speed), an instruction to read SYSCR1 should be located immediately after the instruction to write to SYSCR1. If an instruction to access the on-chip RAM (high-speed) is located immediately after the instruction to write to SYSCR1, normal access is not guaranteed.

Note: When writing to this register, see section 28.4, Usage Notes.

|                |   |   |   |   |       |       |       |       |
|----------------|---|---|---|---|-------|-------|-------|-------|

Note: \* For addresses in each page, see section 27, On-Chip RAM.

## 28.2.8 System Control Register 2 (SYSCR2)

SYSCR2 is an 8-bit readable/writable register that enables or disables write to the on-chip RAM (high-speed). Only byte access is valid.

When an RAMWE bit is set to 1, the corresponding on-chip RAM (high-speed) area is enabled. When an RAMWE bit is cleared to 0, the corresponding on-chip RAM (high-speed) area cannot be written to. In this case, writing to the on-chip RAM (high-speed) is ignored. The initial value of an RAMWE bit is 1.

Note that when clearing the RAME bit to 0 to disable the on-chip RAM (high-speed), be sure to execute an instruction to read from or write to the same arbitrary address in each page before setting the RAMWE bit. If such an instruction is not executed, the data last written to each page may not be written to the on-chip RAM (high-speed). Furthermore, an instruction to access the on-chip RAM (high-speed) should not be located immediately after the instruction to write to SYSCR2. If an on-chip RAM (high-speed) access instruction is set, normal access is not guaranteed.

When setting the RAME bit to 1 to enable write to the on-chip RAM (high-speed), an instruction to read SYSCR2 should be located immediately after the instruction to write to SYSCR2. If an instruction to access the on-chip RAM (high-speed) is located immediately after the instruction to write to SYSCR2, normal access is not guaranteed.

Note: When writing to this register, see section 28.4, Usage Notes.

Note: \* For addresses in each page, see section 27, On-Chip RAM.

### 28.2.9 System Control Register 3 (SYSCR3)

SYSCR3 is an 8-bit readable/writable register that performs the software reset control for the SSI0 to SSI3 and the operation of the crystal resonator for audio. Only byte access is valid.

Note: When writing to this register, see section 28.4, Usage Notes.

|                |            |   |   |   |              |              |              |              |

### 28.2.10 Deep Standby Control Register (DSCTR)

DSCTR is an 8-bit readable/writable register that selects whether to retain the contents of the corresponding area of the on-chip RAM (for data retention) in deep standby mode. Only byte access is valid.

When the RRAMKP3 to 0 bits are set to 1, the contents of the corresponding area of the on-chip RAM (for data retention) are retained in deep standby mode. When these bits are cleared to 0, the contents of the corresponding area of the on-chip RAM (for data retention) are not retained in deep standby mode.

Note: When writing to this register, see section 28.4, Usage Notes.

|                |   |   |   |   |             |             |             |             |

### 28.2.11 Deep Standby Control Register 2 (DSCTR2)

DSCTR2 is an 8-bit readable/writable register that controls the state of the external bus control pins and specifies the startup method when deep standby mode is canceled. Only byte access is valid.

Note: When writing to this register, see section 28.4, Usage Notes.

### 28.2.12 Deep Standby Cancel Source Select Register (DSSSR)

DSSSR is a 16-bit readable/writable register that consists of the bits for selecting the interrupt to cancel deep standby mode. For IRQ0 to IRQ7, the settings are only valid if the pin functions are assigned to PE4 to PE11. Only word access is valid.

**Note:** When writing to this register, see section 28.4, Usage Notes.

### 28.2.13 Deep Standby Cancel Source Flag Register (DSFR)

DSFR is a 16-bit readable/writable register composed of two types of bits. One is the flag that confirms which interrupt canceled deep standby mode. The other is the bit that releases the state of pins after canceling deep standby mode. When deep standby mode is canceled by an interrupt (NMI or IRQ) or a manual reset, this register retains the previous data although power-on reset exception handling is executed. When deep standby mode is canceled by a power-on reset, this register is initialized to H'0000. Only word access is valid.

All flags must be cleared immediately before transition to deep standby mode.

Note: When writing to this register, see section 28.4, Usage Notes.

### 28.2.14 Retention On-Chip RAM Trimming Register (DSRTR)

DSRTR is an 8-bit readable/writable register used to trim the standby current for the on-chip RAM for data retention in deep standby mode. Only byte access is valid.

To retain data on the on-chip RAM for data retention in deep standby mode, be sure to write H'09 to this register before making a transition to deep standby mode.

This register is initialized after the assertion of the  $\overline{\text{RES}}$  pin or exit from deep standby mode.

Note: When writing to this register, see section 28.4, Usage Notes.

## 28.3 Operation

### 28.3.1 Sleep Mode

#### (1) Transition to Sleep Mode

Executing the SLEEP instruction when the STBY bit in STBCR is 0 causes a transition from the program execution state to sleep mode. Although the CPU halts immediately after executing the SLEEP instruction, the contents of its internal registers remain unchanged. The on-chip peripheral modules continue to run in sleep mode. In modes 0, 1 and 3, continuous clock output from the CKIO pin can be specified.

#### (2) Canceling Sleep Mode

Sleep mode is canceled by an interrupt (NMI, IRQ, and on-chip peripheral module), a DMA address error, or a reset (manual reset or power-on reset).

- Canceling by an interrupt

When an NMI, IRQ, or on-chip peripheral module interrupt occurs, sleep mode is canceled and interrupt exception handling is executed. When the priority level of the generated interrupt is equal to or lower than the interrupt mask level that is set in the status register (SR) of the CPU, or the interrupt by the on-chip peripheral module is disabled on the module side, the interrupt request is not accepted and sleep mode is not canceled.

- Canceling by a DMA address error

When a DMA address error occurs, sleep mode is canceled and DMA address error exception handling is executed.

- Canceling by a reset

Sleep mode is canceled by a power-on reset or a manual reset.

### 28.3.2 Software Standby Mode

#### (1) Transition to Software Standby Mode

The LSI switches from a program execution state to software standby mode by executing the SLEEP instruction when the STBY bit and DEEP bit in STBCR are 1 and 0 respectively. In software standby mode, not only the CPU but also the clock and on-chip peripheral modules halt. The clock output from the CKIO pin also stops in clock modes 0, 1 and 3.

The contents of the CPU and cache registers remain unchanged. Some registers of on-chip peripheral modules are, however, initialized. As for the states of on-chip peripheral module registers in software standby mode, see section 30.3, Register States in Each Operating Mode.

The CPU takes one cycle to finish writing to STBCR, and then executes processing for the next instruction. However, it takes one or more cycles to actually write. Therefore, execute a SLEEP instruction after reading STBCR to have the values written to STBCR by the CPU to be definitely reflected in the SLEEP instruction.

The procedure for switching to software standby mode is as follows:

1. Clear the TME bit in the WDT's timer control register (WTCSR) to 0 to stop the WDT.
2. Set the WDT's timer counter (WTCNT) to 0 and the CKS[2:0] bits in WTCSR to appropriate values to secure the specified oscillation settling time.
3. After setting the STBY and DEEP bits in STBCR to 1 and 0 respectively, read STBCR. Then, execute a SLEEP instruction.

## (2) Canceling Software Standby Mode

Software standby mode is canceled by interrupts (NMI or IRQ) or a reset (manual reset or power-on reset). In clock modes 0, 1 and 3, clock signal starts to be output from the CKIO pin.

- Canceling by an interrupt

When the falling edge or rising edge of the NMI pin (selected by the NMI edge select bit (NMIE) in interrupt control register 0 (ICR0) of the interrupt controller (INTC)) or the falling edge or rising edge of an IRQ pin (IRQ7 to IRQ0) (selected by the IRQn sense select bits (IRQn1S and IRQn0S) in interrupt control register 1 (ICR1) of the interrupt controller (INTC)) is detected, clock oscillation is started. This clock pulse is supplied only to the oscillation settling counter (WDT) used to count the oscillation settling time.

After the elapse of the time set in the clock select bits (CKS[2:0]) in the watchdog timer control/status register (WTC SR) of the WDT before the transition to software standby mode, the WDT overflow occurs. Since this overflow indicates that the clock has been stabilized, the clock pulse will be supplied to the entire chip after this overflow. Software standby mode is thus cleared and NMI interrupt exception handling (IRQ interrupt exception handling in case of IRRQ) is started. If the priority level of the generated interrupt is equal to or lower than the interrupt mask level specified in the status register (SR) of the CPU, the interrupt request is not accepted and software standby mode is not canceled.

When canceling software standby mode by the NMI interrupt or IRQ interrupt, set the CKS[2:0] bits so that the WDT overflow period will be equal to or longer than the oscillation settling time.

The clock output phase of the CKIO pin may be unstable immediately after detecting an interrupt and until software standby mode is canceled. When software standby mode is canceled by the falling edge of the NMI pin, the NMI pin should be high when the CPU enters software standby mode (when the clock pulse stops) and should be low when software standby mode is canceled (when the clock is initiated after oscillation settling). When software standby mode is canceled by the rising edge of the NMI pin, the NMI pin should be low when the CPU enters software standby mode (when the clock pulse stops) and should be high when software standby mode is canceled (when the clock is initiated after oscillation settling). (The same applies to the IRQ pin.)

- Canceling by a reset

When the  $\overline{\text{RES}}$  pin is driven low, software standby mode is canceled and the LSI enters the power-on reset state. After that, if the  $\overline{\text{RES}}$  pin is driven high, the power-on reset exception handling is started.

When the  $\overline{\text{MRES}}$  pin is driven low, software standby mode is canceled and the LSI enters the manual reset state. After that, if the  $\overline{\text{MRES}}$  pin is driven high, the manual reset exception handling is started.

Keep the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin low until the clock oscillation settles. The internal clock will continue to be output to the CKIO pin in clock modes 0, 1 and 3.

### (3) Note on Release from Software Standby Mode

Release from software standby mode is triggered by interrupts (NMI and IRQ) or resets (manual reset and power-on reset). If, however, a SLEEP instruction and an interrupt other than NMI and IRQ are generated at the same time, cancellation of software standby mode may occur due to acceptance of the interrupt.

When initiating a transition to software standby mode, make settings so that interrupts are not generated before execution of the SLEEP instruction.

### 28.3.3 Software Standby Mode Application Example

This example describes a transition to software standby mode on the falling edge of the NMI signal, and cancellation on the rising edge of the NMI signal. The timing is shown in figure 28.1.

When the NMI pin is changed from high to low level while the NMI edge select bit (NMIE) in the interrupt control register 0 (ICR0) is set to 0 (falling edge detection), the NMI interrupt is accepted. When the NMIE bit is set to 1 (rising edge detection) by the NMI exception service routine, the STBY and DEEP bits in STBCR are set to 1 and 0 respectively, and a SLEEP instruction is executed, software standby mode is entered. Thereafter, software standby mode is canceled when the NMI pin is changed from low to high level.

**Figure 28.1 NMI Timing in Software Standby Mode (Application Example)**

### 28.3.4 Deep Standby Mode

#### (1) Transition to Deep Standby Mode

The LSI switches from a program execution state to deep standby mode by executing the SLEEP instruction when the STBY bit and DEEP bit in STBCR are set to 1. In deep standby mode, not only the CPU, clocks, and on-chip peripheral modules but also power supply is turned off excluding the on-chip RAM (for data retention) retaining area specified by the RRAMKP3 to RRAMKP0 bits in DSCTR and RTC. This can significantly reduce power consumption. Therefore, data in the registers of the CPU, cache, and on-chip peripheral modules are not retained. Pin state values immediately before the transition to deep standby mode are retained.

The CPU takes one cycle to finish writing to DSCTR, and then executes processing for the next instruction. However, it actually takes one or more cycles to write. Therefore, execute a SLEEP instruction after reading DSCTR to reflect the values written to DSCTR by the CPU in the SLEEP instruction without fail.

The procedure for switching to deep standby mode is as follows. Figure 28.2 also shows its flowchart.

1. To ensure that data is actually retained in deep standby mode by the on-chip RAM (for data retention), set H'09 to DSRTR.
2. Set the RRAMKP3 to RRAMKP0 bits in DSCTR for the corresponding on-chip RAM (for data retention) area that must be retained. Transfer the programs to be retained to the specified areas of the on-chip RAM (for data retention).
3. To cancel deep standby mode by an interrupt, set to 1 the bit in DSSSR corresponding to the pin to be used for cancellation. In this case, also set the input signal detection mode (using interrupt control registers 0 and 1 (ICR0 and ICR1) of the interrupt controller (INTC)) for the pin used for cancellation. In the case of deep standby mode, only rising- or falling-edge detection is valid. (Low-level detection or both-edge detection of the IRQ signal cannot be used to cancel deep standby mode.)
4. Execute read and write of an arbitrary but the same address for each page in the retaining on-chip RAM (for data retention) area. When this is not executed, data last written may not be written to the on-chip RAM (for data retention). If there is a write to the on-chip RAM (for data retention) after this time, execute this processing after the last write to the on-chip RAM (for data retention).
5. Set the STBY and DEEP bits in the STBCR register to 1.
6. Read out the DSFR register after clearing the flag in the DSFR register. Then execute the SLEEP instruction.

**Figure 28.2 Flowchart of Transition to Deep Standby Mode**

## (2) Canceling Deep Standby Mode

Deep standby mode is canceled by interrupts (NMI or an IRQ assigned to PE11 to PE4) or a reset (manual reset or power-on reset). When canceling the mode by the interrupt NMI or IRQ, a power-on reset exception handling is executed instead of an interrupt exception handling. When canceling the mode by manual reset, the same handling is executed.

Figure 28.3 shows the flowchart of canceling deep standby mode.

**Figure 28.3 Flowchart of Canceling Deep Standby Mode**

- Canceling by an interrupt

When the falling edge or rising edge of the NMI pin (selected by the NMI edge select bit (NMIE) in interrupt control register 0 (ICR0) of the interrupt controller (INTC)) or the falling edge or rising edge of an IRQ pin (IRQ7 to IRQ0 assigned to PE11 to PE4) (selected by the IRQn sense select bits (IRQn1S and IRQn0S) in interrupt control register 1 (ICR1) of the interrupt controller (INTC)) is detected, clock oscillation is started after the wait time for the oscillation settling time. After the oscillation settling time has elapsed, deep standby mode is cancelled and the power-on reset exception handling is executed. If the priority level of the generated interrupt is equal to or lower than the interrupt mask level specified in the status register (SR) of the CPU, the interrupt request is not accepted and deep standby mode is not canceled.

The clock output phase of the CKIO pin may be unstable immediately after detecting an interrupt and until deep standby mode is canceled. When deep standby mode is canceled by the falling edge of the NMI pin, the NMI pin should be high when the CPU enters deep standby mode (when the clock pulse stops) and should be low when deep standby mode is canceled (when the clock is initiated after oscillation settling). When deep standby mode is canceled by the rising edge of the NMI pin, the NMI pin should be low when the CPU enters deep standby mode (when the clock pulse stops) and should be high when deep standby mode is canceled (when the clock is initiated after oscillation settling). (The same applies to the IRQ pin.)

In addition, the pin levels of the NMI pin and all interrupt pins (IRQ) selected to cancel deep standby mode (by settings in the deep standby mode cancelation source select register) should be as follows during the transition to deep standby mode, regardless of whether or not those pins are actually used to cancel deep standby mode:

- Pins set to cancel deep standby mode at their rising edge should be low during the transition.
- Pins set to cancel deep standby mode at their falling edge should be high during the transition.

- Canceling with a reset

When the  $\overline{\text{RES}}$  pin is driven low, this LSI leaves deep standby mode and enters the power-on reset state. After this, driving the  $\overline{\text{RES}}$  pin high initiates power-on reset exception handling. Driving the  $\overline{\text{RES}}$  pin low in clock mode 0, 1, or 3 starts output of the internal clock from the CKIO pin.

Driving the  $\overline{\text{MRES}}$  pin low cancels deep standby mode and causes a transition to the power-on reset state. After this, driving the  $\overline{\text{MRES}}$  pin high initiates power-on reset exception handling. In clock mode 0, 1, or 3, output of the internal clock from the CKIO pin also starts by driving the  $\overline{\text{MRES}}$  pin high.

Keep the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin low until the clock oscillation has settled.

### (3) Operation after Canceling Deep Standby Mode

After canceling deep standby mode, the LSI can be activated through the external bus or from the on-chip RAM (for data retention), which can be selected by setting the RAMBOOT bit in DSCTR2. By setting the CS0KEEPE bit, the states of the external bus control pins can be retained even after cancellation of deep standby mode. Table 28.3 shows the pin states after cancellation of deep standby mode according to the setting of each bit. Table 28.4 lists the external bus control pins.

**Table 28.3 Pin States after Cancellation of Deep Standby Mode and System Activation Method by the DSCTR2 Settings**

| CS0KEEPE Bit | RAMBOOT Bit | Activation Method                | Pin States After Cancellation of Deep Standby Mode                                                                                                                                                                                                                         |
|--------------|-------------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | 0           | External bus                     | The states of the external bus control pins are not retained.<br>For other pins, the retention of their states is cancelled when the IOKEEP bit is cleared.                                                                                                                |
| 0            | 1           | On-chip RAM (for data retention) | The states of the external bus control pins are not retained.<br>After cancellation of deep standby mode, the retention of the external bus control pin states is cancelled.<br>For other pins, the retention of their states is cancelled when the IOKEEP bit is cleared. |
| 1            | 0           | —                                | Setting prohibited.                                                                                                                                                                                                                                                        |
| 1            | 1           | On-chip RAM (for data retention) | The states of the external bus control pin are retained.<br>The retention of the states of the external bus control pins and other pins is cancelled when the IOKEEP bit is cleared.                                                                                       |

**Table 28.4 External Bus Control Pins in Different Modes**

| Operating Mode 0<br>(Activation through external 16-bit bus)    | Operating Mode 1<br>(Activation through external 32-bit bus)    |
|-----------------------------------------------------------------|-----------------------------------------------------------------|
| A[20:0]<br>D[15:0]<br>$\overline{CS0}$ , $\overline{RD}$ , CKIO | A[20:2]<br>D[31:0]<br>$\overline{CS0}$ , $\overline{RD}$ , CKIO |

When deep standby mode is canceled by interrupts (NMI or IRQ) or a manual reset, the deep standby cancel source flag register (DSFR) can be used to confirm which interrupt has canceled the mode.

Pins retain the state immediately before the transition to deep standby mode. However, in system activation through the external bus, the retention of the states of the external bus control pins is cancelled so that programs can be fetched after cancellation of deep standby mode. Other pins, after cancellation of deep standby mode, continue to retain the pin states until writing 0 to the IOKEEP bit in DSFR from the same bit. In system activation from the on-chip RAM (for data retention), after cancellation of deep standby mode, both the external bus control pins and other pins continue to retain the pin states until writing 0 to the IOKEEP bit in DSFR from the same bit. Reconfiguration of peripheral functions is required to return to the previous state of deep standby mode. Peripheral functions include all functions such as CPG, INTC, BSC, I/O ports, PFC, and peripheral modules. After the reconfiguration, the retention of the pin state can be canceled and the LSI returns to the state prior to the transition to deep standby mode by reading 1 from the IOKEEP bit in DSFR and then writing 0 to it.

#### **(4) Notes on Transition to Deep Standby Mode**

After deep standby mode is specified, interrupts other than those set as cancel sources in the deep standby cancel source select register are masked. If multiple interrupts are set as cancel sources in the deep standby cancel source select register and more than one of these cancel sources are input, multiple cancel source flags are set.

### 28.3.5 Module Standby Function

#### (1) Transition to Module Standby Function

Setting the standby control register MSTP bits to 1 halts the supply of clocks to the corresponding on-chip peripheral modules. This function can be used to reduce the power consumption in the program execution state and sleep mode. Disable a module before placing it in the module standby mode. In addition, do not access the module's registers while it is in the module standby state.

For details on the states of registers, see section 30.3, Register States in Each Operating Mode.

#### (2) Canceling Module Standby Function

The module standby function can be canceled by clearing each MSTP bit to 0, or by a power-on reset (only possible for RTC, H-UDI, UBC, and DMAC). When taking a module out of the module standby state by clearing the corresponding MSTP bit to 0, read the MSTP bit to confirm that it has been cleared to 0.

## 28.4 Usage Notes

### 28.4.1 Notes on Writing to Registers

When writing to the registers related to power-down modes, note the following.

When writing to the register related to power-down modes, the CPU, after executing a write instruction, executes the next instruction without waiting for the write operation to complete.

Therefore, to reflect the change specified by writing to the register while the next instruction is executed, insert a dummy read of the same register between the register write instruction and the next instruction.

### 28.4.2 Notice about Deep Standby Control Register 2 (DSCTR2)

After (1) power-on reset by  $\overline{\text{RES}}$  pin is released, and (2) the LSI transits to deep standby mode in case that bit 7 (CS0KEEPE) and bit 6 (RAMBOOT) of deep standby control register 2 (DSCTR2) are set to "1", these bits become unable to be written as "0" since then.

To write these as "0", it is necessary to assert  $\overline{\text{RES}}$  pin to low.

### 28.4.3 Notice about Power-On Reset Exception Handling

- After (1) power-on reset by  $\overline{\text{RES}}$  pin is released, (2) the LSI transit to deep standby mode in case that bit 6 (RAMBOOT) of deep standby control register 2 (DSCTR2) is set to "1", (3) the deep standby mode is cancelled, and (4) power-on reset by WDT or H-UDI reset is occurred before power-on reset by  $\overline{\text{RES}}$  pin is executed again, then the behavior of the power-on reset exception handling is as table 28.5. So if applicable as above case, PC and SP are necessary to be retained in the area of on-chip RAM for data retention.

**Table 28.5 Power-On Reset Exception Handling**

| Address where<br>the program counter (PC) is fetched | Address where<br>the stack pointer (SP) is fetched |
|------------------------------------------------------|----------------------------------------------------|
| H'FFFF8000                                           | H'FFFF8004                                         |

- After (1) power-on reset by  $\overline{\text{RES}}$  pin is released, (2) the LSI transit to deep standby mode, and (3) the deep standby mode is cancelled, if there is a possibility that power-on reset by WDT or H-UDI reset is occurred before power-on reset by  $\overline{\text{RES}}$  pin is executed again, the settings of WDT or H-UDI should be done in the condition that bit 15 (IOKEEP) and bits 9~0 of deep standby cancel source flag register (DSFR) are all cleared after canceling deep standby mode (if some bits are 1, please write these as "0").

If (1) the setting of WDT or H-UDI is done in the condition that IOKEEP bit is not 0, and (2) power-on reset by WDT or H-UDI reset is occurred before power-on reset by  $\overline{\text{RES}}$  pin is executed again, the pin status of the pins, whose pin status are retained in deep standby mode and which are not in table 28.4, are kept retained. Additionally, in the case that bit 7 (CS0KEEPE) of deep standby control register 2 (DSCTR2) are set to "1", the pin status of the pins in table 28.4 are also keep retained.

If (1) the settings of WDT or H-UDI is done in the condition that bits 9~0 are not all 0, and (2) power-on reset by WDT or H-UDI reset is occurred before power-on reset by  $\overline{\text{RES}}$  pin is executed again, the internal information about the deep standby canceling source is not cleared, and deep standby mode are cancelled by the wrong canceling source when the LSI attempt to transit to deep standby mode since then.

## Section 29 User Debugging Interface (H-UDI)

This LSI incorporates a user debugging interface (H-UDI) for emulator support.

### 29.1 Features

The user debugging interface (H-UDI) has reset and interrupt request functions.

The H-UDI in this LSI is used for emulator connection. Refer to the emulator manual for the method of connecting the emulator.

Figure 29.1 shows a block diagram of the H-UDI.

**Figure 29.1 Block Diagram of H-UDI**

## 29.2 Input/Output Pins

**Table 29.1 Pin Configuration**

| Pin Name                            | Symbol                      | I/O    | Function                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------|-----------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Clock pin for H-UDI serial data I/O | TCK                         | Input  | Data is serially supplied to the H-UDI from the data input pin (TDI), and output from the data output pin (TDO), in synchronization with this clock.                                                                                                                                                                                                                                  |
| Mode select input pin               | TMS                         | Input  | The state of the TAP control circuit is determined by changing this signal in synchronization with TCK. For the protocol, see figure 29.2.                                                                                                                                                                                                                                            |
| H-UDI reset input pin               | $\overline{\text{TRST}}$    | Input  | Input is accepted asynchronously with respect to TCK, and when low, the H-UDI is reset. $\overline{\text{TRST}}$ must be low for a constant period when power is turned on regardless of using the H-UDI function. See section 29.4.2, Reset Configuration, for more information.                                                                                                     |
| H-UDI serial data input pin         | TDI                         | Input  | Data transfer to the H-UDI is executed by changing this signal in synchronization with TCK.                                                                                                                                                                                                                                                                                           |
| H-UDI serial data output pin        | TDO                         | Output | Data read from the H-UDI is executed by reading this pin in synchronization with TCK. The initial value of the data output timing is the TCK falling edge. This can be changed to the TCK rising edge by inputting the TDO change timing switch command to SDIR. See section 29.4.3, TDO Output Timing, for more information.                                                         |
| ASE mode select pin                 | $\overline{\text{ASEMD}}^*$ | Input  | If a low level is input at the $\overline{\text{ASEMD}}$ pin while the $\overline{\text{RES}}$ pin is asserted, ASE mode is entered; if a high level is input, product chip mode is entered. In ASE mode, dedicated emulator function can be used. The input level at the $\overline{\text{ASEMD}}$ pin should be held for at least one cycle after $\overline{\text{RES}}$ negation. |

Note: \* When the emulator is not in use, fix this pin to the high level.

## 29.3 Register Descriptions

The H-UDI has the following registers.

**Table 29.2 Register Configuration**

| Register Name        | Abbreviation | R/W | Initial Value | Address    | Access Size |
|----------------------|--------------|-----|---------------|------------|-------------|
| Bypass register      | SDBPR        | —   | —             | —          | —           |
| Instruction register | SDIR         | R   | H'EFFD        | H'FFFE2000 | 16          |

### 29.3.1 Bypass Register (SDBPR)

SDBPR is a 1-bit register that cannot be accessed by the CPU. When SDIR is set to BYPASS mode, SDBPR is connected between H-UDI pins TDI and TDO. The initial value is undefined.

### 29.3.2 Instruction Register (SDIR)

SDIR is a 16-bit read-only register. It is initialized by  $\overline{\text{TRST}}$  assertion or in the TAP test-logic-reset state, and can be written to by the H-UDI irrespective of the CPU mode. Operation is not guaranteed if a reserved command is set in this register. The initial value is H'EFFD.

|                |         |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |
|----------------|---------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|
| Bit:           | 15      | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                | TI[7:0] |    |    |    |    |    |    |    | - | - | - | - | - | - | - | - |
| Initial value: | 1*      | 1* | 1* | 0* | 1* | 1* | 1* | 1* | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 1 |
| R/W:           | R       | R  | R  | R  | R  | R  | R  | R  | R | R | R | R | R | R | R | R |

Note: \* The initial value of the TI[7:0] bits is a reserved value. When setting a command, the TI[7:0] bits must be set to another value.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                   |

## 29.4 Operation

### 29.4.1 TAP Controller

Figure 29.2 shows the internal states of the TAP controller.

**Figure 29.2 TAP Controller State Transitions**

**Note:** The transition condition is the TMS value at the rising edge of TCK. The TDI value is sampled at the rising edge of TCK; shifting occurs at the falling edge of TCK. For details on change timing of the TDO value, see section 29.4.3, TDO Output Timing. The TDO is at high impedance, except with shift-DR and shift-IR states. During the change to  $\overline{\text{TRST}} = 0$ , there is a transition to test-logic-reset asynchronously with TCK.

## 29.4.2 Reset Configuration

**Table 29.4 Reset Configuration**

| $\overline{\text{ASEMD}}^{*1}$ | $\overline{\text{RES}}$ | $\overline{\text{TRST}}$ | Chip State                     |
|--------------------------------|-------------------------|--------------------------|--------------------------------|
| H                              | L                       | L                        | Power-on reset and H-UDI reset |
|                                |                         | H                        | Power-on reset                 |
|                                | H                       | L                        | H-UDI reset only               |
|                                |                         | H                        | Normal operation               |
| L                              | L                       | L                        | Reset hold* <sup>2</sup>       |
|                                |                         | H                        | Power-on reset                 |
|                                | H                       | L                        | H-UDI reset only               |
|                                |                         | H                        | Normal operation               |

Notes: 1. Performs product chip mode and ASE mode settings

$\overline{\text{ASEMD}} = \text{H}$ , product chip mode

$\overline{\text{ASEMD}} = \text{L}$ , ASE mode

2. In ASE mode, reset hold is entered if the  $\overline{\text{TRST}}$  pin is driven low while the  $\overline{\text{RES}}$  pin is negated. In this state, the CPU does not start up. When  $\overline{\text{TRST}}$  is driven high, H-UDI operation is enabled, but the CPU does not start up. The reset hold state is cancelled by a power-on reset.

## 29.4.3 TDO Output Timing

The initial value of the TDO change timing is to perform data output from the TDO pin on the TCK falling edge. However, setting a TDO change timing switch command in SDIR via the H-UDI pin and passing the Update-IR state synchronizes the TDO change timing to the TCK rising edge. Hereafter, to synchronize the change timing of TD0 to the falling edge of TCK, the  $\overline{\text{TRST}}$  pin must be simultaneously asserted with the power-on reset. In a case of power-on reset by the  $\overline{\text{RES}}$  pin, the sync reset is still in operation for a certain period in the LSI even after the  $\overline{\text{RES}}$  pin is negated. Thus, if the  $\overline{\text{TRST}}$  pin is asserted immediately after the negate of the  $\overline{\text{RES}}$  pin, the TD0 change timing switch command is cleared, resulting the TD0 change timing synchronized with the falling edge of TCK. To prevent this, make sure to put a period of 20 times of  $t_{\text{cyc}}$  or longer between the signal change timing of the  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  pins.

**Figure 29.3 H-UDI Data Transfer Timing**

### 29.4.4 H-UDI Reset

An H-UDI reset is executed by setting an H-UDI reset assert command in SDIR. An H-UDI reset is of the same kind as a power-on reset. An H-UDI reset is released by setting an H-UDI reset negate command. The required time between the H-UDI reset assert command and H-UDI reset negate command is the same as time for keeping the RES pin low to apply a power-on reset.

**Figure 29.4 H-UDI Reset**

### 29.4.5 H-UDI Interrupt

The H-UDI interrupt function generates an interrupt by setting a command from the H-UDI in SDIR. An H-UDI interrupt is a general exception/interrupt operation, resulting in fetching the exception service routine start address from the exception handling vector table, jumping to that address, and starting program execution from that address. This interrupt request has a fixed priority level of 15.

H-UDI interrupts are accepted in sleep mode, but not in software standby mode.

## 29.5 Usage Notes

1. An H-UDI command, once set, will not be modified as long as another command is not set again from the H-UDI. If the same command is to be set continuously, the command must be set after a command (BYPASS mode, etc.) that does not affect chip operations is once set.
2. In software standby mode and H-UDI module standby state, all of the functions in the H-UDI cannot be used. To retain the TAP status before and after standby mode, keep TCK high before entering standby mode.
3. Regardless of whether or not the H-UDI is in use, be sure to keep the  $\overline{\text{TRST}}$  pin low to initialize the H-UDI when power is supplied or when assertion of the  $\overline{\text{RES}}$  signal cancels deep standby mode.
4. When the TDO change timing switch command is set and the  $\overline{\text{TRST}}$  pin is asserted immediately after and the  $\overline{\text{RES}}$  pin is negated, the TDO change timing switch command may be cleared. To prevent this, make sure to insert an interval of  $20 t_{\text{cyc}}$  or more between the signal changes of the  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  pins when the TDO change timing switch command is set. Make sure to put  $20 t_{\text{cyc}}$  or more between the signal change timing of the  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  pins. For details, see section 29.4.3, TDO Output Timing.
5. When starting the TAP controller after the negation of the  $\overline{\text{TRST}}$  pin, make sure to allow 200 ns or more after the negation.

## Section 30 List of Registers

This section gives information on the on-chip I/O registers of this LSI in the following structures.

1. Register Addresses (by functional module, in order of the corresponding section numbers)
  - Registers are described by functional module, in order of the corresponding section numbers.
  - Access to reserved addresses which are not described in this register address list is prohibited.
  - When registers consist of 16 or 32 bits, the addresses of the MSBs are given when big endian mode is selected.
2. Register Bits
  - Bit configurations of the registers are described in the same order as the Register Addresses (by functional module, in order of the corresponding section numbers).
  - Reserved bits are indicated by — in the bit name.
  - No entry in the bit-name column indicates that the whole register is allocated as a counter or for holding data.
3. Register States in Each Operating Mode
  - Register states are described in the same order as the Register Addresses (by functional module, in order of the corresponding section numbers).
  - For the initial state of each bit, refer to the description of the register in the corresponding section.
  - The register states described are for the basic operating modes. If there is a specific reset for an on-chip peripheral module, refer to the section on that on-chip peripheral module.
4. Notes when Writing to the On-Chip Peripheral Modules
  - To access an on-chip module register, two or more peripheral module clock (Pφ) cycles are required. Care must be taken in system design. When the CPU writes data to the internal peripheral registers, the CPU performs the succeeding instructions without waiting for the completion of writing to registers. For example, a case is described here in which the system is transferring to the software standby mode for power savings. To make this transition, the SLEEP instruction must be performed after setting the STBY bit in the STBCR register to 1. However a dummy read of the STBCR register is required before executing the SLEEP instruction. If a dummy read is omitted, the CPU executes the SLEEP instruction before the STBY bit is set to 1, thus the system enters sleep mode not software standby mode. A dummy read of the STBCR register is indispensable to complete writing to the STBY bit. To reflect the change by internal peripheral registers while performing the succeeding instructions, execute a dummy read of registers to which write instruction is given and then perform the succeeding instructions.

### 30.1 Register Addresses (by functional module, in order of the corresponding section numbers)

| Module Name | Register Name                   | Abbreviation | Number of Bits | Address    | Access Size |
|-------------|---------------------------------|--------------|----------------|------------|-------------|
| CPG         | Frequency control register      | FRQCR        | 16             | H'FFFE0010 | 16          |
| INTC        | Interrupt control register 0    | ICR0         | 16             | H'FFFE0800 | 16, 32      |
|             | Interrupt control register 1    | ICR1         | 16             | H'FFFE0802 | 16, 32      |
|             | Interrupt control register 2    | ICR2         | 16             | H'FFFE0804 | 16, 32      |
|             | IRQ interrupt request register  | IRQRR        | 16             | H'FFFE0806 | 16, 32      |
|             | PINT interrupt enable register  | PINTER       | 16             | H'FFFE0808 | 16, 32      |
|             | PINT interrupt request register | PIRR         | 16             | H'FFFE080A | 16, 32      |
|             | Bank control register           | IBCR         | 16             | H'FFFE080C | 16, 32      |
|             | Bank number register            | IBNR         | 16             | H'FFFE080E | 16, 32      |
|             | Interrupt priority register 01  | IPR01        | 16             | H'FFFE0818 | 16, 32      |
|             | Interrupt priority register 02  | IPR02        | 16             | H'FFFE081A | 16, 32      |
|             | Interrupt priority register 05  | IPR05        | 16             | H'FFFE0820 | 16, 32      |
|             | Interrupt priority register 06  | IPR06        | 16             | H'FFFE0C00 | 16, 32      |

- Notes:
1. When normal memory, SRAM with byte selection, or address/data multiplex I/O (MPX-I/O) is the memory type
  2. When burst ROM (clock asynchronous) is the memory type
  3. When burst ROM (clock synchronous) is the memory type
  4. Normal memory, SRAM with byte selection is the memory type
  5. When SDRAM is the memory type
  6. When PCMCIA is the memory type
  7. When burst MPX-I/O is the memory type
  8. When MCR15 = 0
  9. When MCR15 = 1

10. In command access mode

11. In sector access mode

### 30.3 Register States in Each Operating Mode

| Module Name | Register Abbreviation | Power-On Reset            | Manual Reset           | Deep Standby           | Software Standby       | Module Standby | Sleep                  |

- Notes:
1. Retains the previous value after an internal power-on reset by means of the WDT.
  2. The BN3 to BN0 bits are initialized.
  3. Flag handling continues.
  4. Counting up continues.
  5. Transfer operations can be continued.
  6. Bits RTCEN and START are retained.
  7. Bits BC2 to BC0 are initialized.
  8. Since pin states are read out on the port A data register (PADRL) and the port registers, values in these registers are neither retained nor initialized.
  9. Initialized by  $\overline{\text{TRST}}$  assertion or in the Test-Logic-Reset state of the TAP controller.
  10. Initialized by  $\overline{\text{RES}}$  assertion and retains the previous value after an internal power-on reset by means of the H-UDI reset assert command or by means of the WDT.

## Section 31 Electrical Characteristics

### 31.1 Absolute Maximum Ratings

**Table 31.1 Absolute Maximum Ratings**

| Item                                                    | Symbol           | Value                   | Unit                    |   |
|---------------------------------------------------------|------------------|-------------------------|-------------------------|---|
| Power supply voltage (I/O)                              | $PV_{CC}$        | −0.3 to 4.6             | V                       |   |
| Power supply voltage (Internal)                         | $V_{CC}$         | −0.3 to 1.7             | V                       |   |
| PLL power supply voltage                                | $PLL V_{CC}$     | −0.3 to 1.7             | V                       |   |
| Analog power supply voltage                             | $AV_{CC}$        | −0.3 to 4.6             | V                       |   |
| Analog reference voltage                                | $AV_{ref}$       | −0.3 to $AV_{CC} + 0.3$ | V                       |   |
| USB transceiver analog power supply voltage (I/O)       | $USBAPV_{CC}$    | −0.3 to 4.6             | V                       |   |
| USB transceiver digital power supply voltage (I/O)      | $USBDPV_{CC}$    | −0.3 to 4.6             | V                       |   |
| USB transceiver analog power supply voltage (internal)  | $USBAV_{CC}$     | −0.3 to 1.7             | V                       |   |
| USB transceiver digital power supply voltage (internal) | $USBDV_{CC}$     | −0.3 to 1.7             | V                       |   |
| Input voltage                                           | Analog input pin | $V_{AN}$                | −0.3 to $AV_{CC} + 0.3$ | V |
|                                                         | VBUS             | $V_{in}$                | −0.3 to 5.5             | V |
|                                                         | Other input pins | $V_{in}$                | −0.3 to $PV_{CC} + 0.3$ | V |
| Operating temperature                                   | $T_{opr}$        | −20 to +85              | °C                      |   |
| Storage temperature                                     | $T_{stg}$        | −55 to +125             | °C                      |   |

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

## 31.2 Power-on/Power-off Sequence

**Figure 31.1 Power-on/Power-off Sequence**

**Table 31.2 Time for Power-on/Power-off Sequence**

| Item                 | Symbol    | Min. | Max. | Unit |
|----------------------|-----------|------|------|------|
| State undefined time | $t_{unc}$ | —    | 100  | ms   |

**Note:** It is recommended that the 1.2-V power supply ( $V_{CC}$ ,  $PLL V_{CC}$ ,  $USBAV_{CC}$ , and  $USBDV_{CC}$ ) and the 3.3-V power supply ( $PV_{CC}$ ,  $AV_{CC}$ ,  $USBAPV_{CC}$ ,  $USBDPV_{CC}$ ) are turned on and off nearly simultaneously.

An indefinite period of time appears, from the time that power is turned on to the time that both of the 1.2-V power supply and the 3.3-V power supply rise to the Min. voltage (1.1 V for 1.2-V power supply and 3.0 V for 3.3-V power supply), or from the time that either of the 1.2-V power supply or the 3.3-V power supply is turned off and passes the Min. voltage (1.1 V for 1.2-V power supply and 3.0 V for 3.3-V power supply) to the time that both of the 1.2-V power supply and the 3.3-V power supply fall to GND.

During these periods, states of output pins and in-out pins and internal states become undefined. So it should be as short as possible. Also design the system so that these undefined states do not cause an overall malfunction.

### 31.3 DC Characteristics

**Table 31.3 DC Characteristics (1) [Common Items]**

Conditions:  $V_{CC} = PLLV_{CC} = USBDV_{CC} = 1.1$  to  $1.3$  V,  $PV_{CC} = USBDPV_{CC} = 3.0$  to  $3.6$  V,  
 $AV_{CC} = 3.0$  to  $3.6$  V,  $USBAV_{CC} = 1.1$  to  $1.3$  V,  $USBAPV_{CC} = 3.0$  to  $3.6$  V,  
 $V_{SS} = PLLV_{SS} = PV_{SS} = AV_{SS} = USBDV_{SS} = USBAV_{SS} = USBDPV_{SS} =$   
 $USBAPV_{SS} = 0$  V,  $T_a = -20$  to  $85$  °C

| Item                         |                       | Symbol           | Min. | Typ. | Max. | Unit | Test Conditions                                                                        |
|------------------------------|-----------------------|------------------|------|------|------|------|----------------------------------------------------------------------------------------|
| Power supply voltage         |                       | $PV_{CC}$        | 3.0  | 3.3  | 3.6  | V    |                                                                                        |
|                              |                       | $V_{CC}$         | 1.1  | 1.2  | 1.3  | V    |                                                                                        |
| PLL power supply voltage     |                       | $PLLV_{CC}$      | 1.1  | 1.2  | 1.3  | V    |                                                                                        |
| Analog power supply voltage  |                       | $AV_{CC}$        | 3.0  | 3.3  | 3.6  | V    |                                                                                        |
| USB power supply voltage     |                       | $USBAPV_{CC}$    | 3.0  | 3.3  | 3.6  | V    |                                                                                        |
|                              |                       | $USBDPV_{CC}$    |      |      |      |      |                                                                                        |
|                              |                       | $USBAV_{CC}$     | 1.1  | 1.2  | 1.3  | V    |                                                                                        |

Caution: When the A/D converter or D/A converter is not in use, the  $AV_{CC}$  and  $AV_{SS}$  pins should not be open.

- Notes: 1. The supply current values are when all output pins and pins with the pull-up function are unloaded.
2.  $I_{CC}$ ,  $I_{sleep}$ , and  $I_{sstby}$  represent the total currents supplied in the  $V_{CC}$  and  $PLL V_{CC}$  systems.
3.  $I_{dstby}$  (1.2-V current) represents the total currents supplied in the  $V_{CC}$ ,  $PLL V_{CC}$ ,  $USBAV_{CC}$ , and  $USBDV_{CC}$ .
4.  $I_{dstby}$  (3.3-V current) represents the total currents supplied in the  $PV_{CC}$ ,  $AV_{CC}$ ,  $USBAPV_{CC}$ , and  $USBDPV_{CC}$ .

- Notes: 1. The maximum value (fmax) of  $B\phi$  (external bus clock) depends on the number of wait cycles and the system configuration of your board.
2.  $1/2 t_{cyc}$  indicated in minimum and maximum values for the item of delay, setup, and hold times represents a half cycle from the rising edge with a clock. That is,  $1/2 t_{cyc}$  describes a reference of the falling edge with a clock.

| Command output off to status read transition time | $t_{NCDFSR}$ | $3.5 \times t_{fcyc}$ | —    | ns   |                      |
| Status read setup time                            | $t_{NSTS}$   | $2.5 \times t_{fcyc}$ | —    | ns   |                      |

Note:  $t_{fcyc}$  indicates the period of one cycle of the FLCTL clock.

$t_{wfcyc}$  indicates the period of one cycle of the FLCTL clock when the value of the NANDWF bit is 0. On the other hand,  $t_{wfcyc}$  indicates the period of two cycles of the FLCTL clock when the value of the NANDWF bit is 1.

$t_{pcyc}$  indicates the period of one cycle of the peripheral clock (Pφ).

## 31.7 Usage Note

Mount a multilayer ceramic capacitor between a pair of the power supply pins as a bypass capacitor. These capacitors must be placed as close as the power supply pins of the LSI. The capacitance of the capacitors should be used between 0.1  $\mu\text{F}$  and 0.33  $\mu\text{F}$  (recommended values). For details of the capacitor related to the crystal resonator, see section 4.8, Notes on Board Design.

Figure 31.83 is an example of externally allocated capacitors.

Figure 31.83 Example of Externally Allocated Capacitors

# Appendix

## [Legend]

I: Input

O: Output

H: High-level output

L: Low-level output

Z: High-impedance

K: Input pins become high-impedance, and output pins retain their state.

Notes: 1. Indicates the power-on reset by low-level input to the  $\overline{\text{RES}}$  pin. The pin states after a power-on reset by the H-UDI reset assert command or WDT overflow are the same as the initial pin states at normal operation (see section 25, Pin Function Controller (PFC)).

2. After the chip has shifted to the power-on reset state from deep standby mode by the input on any of pins NMI, MRES, and IRQ7 to IRQ0, the pins retain the state until the IOKEEP bit in the deep standby cancel source flag register (DSFR) is cleared (see section 28, Power-Down Modes).
3. The week keeper circuits included in the I/O pins are turned off.
4. When pins for the connection with a crystal resonator are not used, the input pins (EXTAL, RTC\_X1, AUDIO\_X1, and USB\_X1) must be fixed (pulled up, pulled down, connected to power supply, or connected to ground) and the output pins (XTAL, RTC\_X2, AUDIO\_X2, and USB\_X2) must be open.
5. The initial pin function depends on the data bus width of area 0 (see section 25, Pin Function Controller (PFC)).
6. Depends on the setting of the CKOEN bit in the frequency control register (FRQCR) of the CPG (see section 4, Clock Pulse Generator (CPG)).
7. Depends on the setting of the HIZ bit in the standby control register 3 (STBCR3) (see section 28, Power-Down Modes).
8. Depends on the setting of the HIZMEM bit in the common control register (CMNCR) of the BSC (see section 9, Bus State Controller (BSC)).
9. Depends on the setting of the HIZCNT bit in the common control register (CMNCR) of the BSC (see section 9, Bus State Controller (BSC)).
10. Depends on the setting of the corresponding bit in the deep standby cancel source select register (DSSSR) (see section 28, Power-Down Modes).
11. Depends on the setting of the RTCEN bit in the RTC control register 2 (RCR2) of the RTC (see section 14, Realtime Clock (RTC)).
12. Depends on the AXTALE bit in the standby control register (STBCR) (see section 28, Power-Down Modes).
13. When the CS0KEEPE bit in the deep standby control register 2 (DSCTR2) is 1, this pin retains the state of deep standby mode. When the CS0KEEPE bit is 0, this pin enters the state of a power-on reset (see section 28, Power-Down Modes).
14. Z when the TAP controller of the H-UDI is neither the Shift-DR nor Shift-IR state.
15. These are the pin states in product chip mode ( $\overline{\text{ASEMD}} = \text{H}$ ). See the Emulation Manual for the pin states in ASE mode ( $\overline{\text{ASEMD}} = \text{L}$ ).

## B. Treatment of Unused Pins

**Table B.1 Handling of Pins that Are Not in Use (Except for H-UDI and Emulator Interface Pins)**

| Pin                                                                                                                     | Handling                                                                                                                                                |

| NMI                                                                                                                     | Fix this pin at a high level (pull up or connect to the power-supply level).                                                                            |
| DP, DM, and VBUS                                                                                                        | Connect these pins to USBDPVss.                                                                                                                         |
| REFRIN                                                                                                                  | Connect this pin, via a $5.6\text{ k}\Omega \pm 20\%$ resistor, to USBAPVss.                                                                            |
| Dedicated USB power pins (USBAPVcc, USBAPVss, USBDPVcc, USBDPVss, USBAVcc, USBAVss, USBDVcc, USBDVss, USBUVcc, USBUVss) | Connect the power-supply pins to the power-supply level and ground pins to the ground level.                                                            |
| AVref                                                                                                                   | Connect this pin to AVcc.                                                                                                                               |
| Dedicated A/D and D/A power pins (AVcc, AVss)                                                                           | Connect the power-supply pin to the power-supply level and ground pin to the ground level.                                                              |
| Pins with weak keeper or pull-up                                                                                        | Open-circuit                                                                                                                                            |
| Dedicated input pins other than those listed above                                                                      | Fix the level on the pins (pull them up or down, or connect them to the power-supply or ground level).                                                  |
| Input/output pins other than those listed above                                                                         | Make the input-pin settings and then fix the level (pull them up or down); alternatively, make the output-pin settings and leave the pins open-circuit. |
| Dedicated output pins other than those listed above                                                                     | Open-circuit                                                                                                                                            |

Note: It is recommended that the values of pull-up or pull-down resistors are in the range from 4.7 k $\Omega$  to 100 k $\Omega$ .

**Table B.2 Handling of Pins that Are Not in Use (When H-UDI Is Not Used in Product Chip Mode)**

| Pin                                                                          | Handling                                                                                                                                                                                     |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\overline{\text{ASEMD}}$                                                    | Fix this pin at a high level (pull up or connect to the powersupply level).                                                                                                                  |
| $\overline{\text{TRST}}$                                                     | Pull-down with a 1 k $\Omega$ resistor.<br>Or, fix this pin at a low level when power-up or release the deep-standby mode by $\overline{\text{RES}}$ pin, and open-circuit other than above. |
| TCK, TMS, TDI, TDO,<br>$\overline{\text{ASEBRKAK}}/\overline{\text{ASEBRK}}$ | Open-circuit                                                                                                                                                                                 |

Notes: 1. When using the H-UDI, handle these pins as described in the manual for the emulator.  
2. It is recommended that the values of pull-up or pull-down resistors are in the range from 4.7 k $\Omega$  to 100 k $\Omega$ .

C. Package Dimensions

The package dimension that is shown in the Renesas Semiconductor Package Data Book has priority.

5.2.2 Types of Reset

127

Table and table note amended

Table 5.6 Reset States

| Type           | Conditions for Transition to Reset State |                                              |      |                | Internal States           |               |                                                |                            |
|----------------|------------------------------------------|----------------------------------------------|------|----------------|---------------------------|---------------|------------------------------------------------|----------------------------|
|                | RES                                      | H-UDI Command                                | MRES | WDT Overflow   | CPU                       | Other Modules | On-Chip High-Speed RAM                         | On-Chip Data Retention RAM |
| Power-on reset | Low                                      | —                                            | —    | —              | Initialized               | Initialized   | Initialized or retained contents <sup>*2</sup> | Initialized                |
|                | High                                     | H-UDI reset assert command is set            | —    | —              | Initialized               | Initialized   | Initialized or retained contents <sup>*2</sup> | Initialized                |
|                | High                                     | Command other than H-UDI reset assert is set | —    | Power-on reset | Initialized <sup>*1</sup> | —             | Initialized or retained contents <sup>*2</sup> | Initialized                |
| Manual reset   | High                                     | Command other than H-UDI reset assert is set | Low  | —              | Initialized <sup>*1</sup> | —             | Retained contents                              | Retained contents          |
|                | High                                     | Command other than H-UDI reset assert is set | High | Manual reset   | Initialized <sup>*1</sup> | —             | Retained contents                              | Retained contents          |

Notes:

1. See section 30.3, Register States in Each Operating Mode.

2. Data are retained when the setting of either the RAME or RAMWE bit is disabled.

5.3.2 Address Error Exception Handling

132

Note amended

Note:

\* In the case of address error related to data read/write. In the case of address error related to instruction fetch, if the bus cycle in which the address error occurred doesn't end until the entire three above-mentioned operations end, the CPU will start address error exception handling again until the bus cycle in which the address error occurred ends.

5.9.4 Interrupt Control via Modification of Interrupt Mask Bits

144

Section newly added

9.3.1 Address Map

241

Table amended

Table 9.2 Address Map

| Internal Address         | Space | Memory to be Connected                     | Cache |
|--------------------------|-------|--------------------------------------------|-------|
| H'40000000 to H'FFFBFFFF | Other | On-chip RAM, reserved area*                | —     |
| H'FFFC0000 to H'FFFFFFF  | Other | On-chip peripheral modules, reserved area* | —     |

9.3.2 Data Bus Width and Related Pin Settings for Each Area

241, 242

Section title and description replaced

9.4.1 Common Control Register (CMNCR)

246

Bit table amended

| Bit | Bit Name | Initial Value | R/W | Description         |
|-----|----------|---------------|-----|---------------------|
| 1   | HIZMEM   | 0             | R/W | Hi-Z Memory Control |

Specifies the pin state in software standby mode or deep standby mode for A25 to A0, BS, CSn, CE2x, RD/WR, WEn/DQMxx/AH, RD, and FRAME. ...

| Item                                                        | Page       | Revision (See Manual for Details)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |               |     |             |        |            |    |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Notes:** 1. The number of idle cycles is determined by the setting of the CSnWCR.HW[1:0] bits on the previous cycle. The number of idle cycles will be the number shown at the left when HW[1:0] ≠ B'00, will be the number shown at the right when HW[1:0] = B'00. Also, for CSn spaces for which the CSnWCR.HW[1:0] bits do not exist, the number of idle cycles shown at the right will be used.

2. The number of idle cycles is determined by the setting of the CSnWCR.TEH[3:0] bits on the previous cycle. The number of idle cycles will be the number shown at the left when TEH[3:0] ≠ B'0000, will be the number shown at the right when TEH[3:0] = B'0000.

### Figure 9.54 Comparison between Estimated Idle Cycles and Actual Value

| 11.3.16 Timer Output Master Enable Register (TOER)                               | 501                                                         | Description added<br>... Set TOER of CH3 and CH4 prior to setting TIOR of CH3 and CH4. Set TOER when count operation of TCNT channels 3 and 4 is halted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                               |                                                                                                                                                                                                                                                                                          |                 |          |                      |                 |                           |                                               |                               |                                                                                                                                                                                                                                                                                          |                |                           |               |                                                             |                                                                                                                                                                    |      |             |                 |              |                                                         |          |      |                           |                               |              |                                              |          |      |             |                           |      |      |      |      |      |                |      |      |      |      |      |

The waveform in this case has a positive phase with a 100% on-state. 0% duty output is performed when the compare register value is set to the same value as TGRA_3. ...                                                                                                                                                                                                                                                                                                                                                     |
| (n) Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode                                                                                                                                                      | 576  | Description added<br><br>When using the initial output suppression function, make sure to set compare registers TGRB_3, TGRA_4, and TGRB_4 to a value twice or more the setting of dead time data register TDDR. If synchronous clearing occurs with the compare registers set to a value less than twice the setting of TDDR, the PWM output dead time may be too short (or nonexistent) or illegal active-level PWM negative-phase output may occur during the initial output suppression interval. For details, see section 11.7.23, Notes on Output Waveform Control During Synchronous Counter Clearing in Complementary PWM Mode. |

[Legend]

Blank: No setting possible, or the electrical characteristics of the SH7203 cannot be satisfied regardless of the device being communicated with.

—: Setting possible, but error occurs

23.3.4

Test Mode Register (TESTMODE)

1112

Bit table amended

| Bit    | Bit Name  | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|-----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 to 0 | UTST[3:0] | 0000          | R/W | Test Mode<br><br>Table 23.4 shows test mode operation of this module. These bits control the USB test signal output in high-speed mode.<br><br>[When the host controller function is selected]<br>When the host controller function is selected, these bits may be set after writing 1 to DCFM and DMRPD, and 0 to DPRPU. Writing to these bits terminates high-speed operation.<br>Use the following procedure to set these bits:<br>(1) Perform a power-on reset.<br>(2) Writing 1 to DCFM and DMRPD, and 0 to DPRPU. (It is not necessary to set HSE to 1.)<br>(3) Set USBE to 1.<br><br>... |

23.3.7

FIFO Port Select Registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL)

1121

Table note amended

Notes: 1. Only reading 0 and writing 1 are valid. Before setting REW to 1, confirm that FRDY is set to 1.

(2) D0FIFOSEL, D1FIFOSEL

23.3.8

FIFO Port Control Registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR)

1122

Table note amended

Notes: 1. Only 1 can be written to. Before setting BVAL to 1, confirm that FRDY is set to 1.

23.3.12

Interrupt Enabled Register 1 (INTENB1)

1128

Bit table amended

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Revision (See Manual for Details)

28.3.4 Deep Standby Mode

1433

Description amended  
  
... If multiple interrupts are set as cancel sources in the deep standby cancel source select register and more than one of these cancel sources are input, multiple cancel source flags are set.

30.1 Register Addresses (by functional module, in order of the corresponding section numbers)

1454

Table amended

| Module Name | Register Name                          | Abbreviation | Number of Bits | Address    | Access Size |
|-------------|----------------------------------------|--------------|----------------|------------|-------------|
| WDT         | Watchdog timer control/status register | WTCSCR       | 8              | H'FFFE0000 | 8, 16       |
|             | Watchdog timer counter                 | WTCNT        | 8              | H'FFFE0002 | 8, 16       |
|             | Watchdog reset control/status register | WRCSR        | 8              | H'FFFE0004 | 8, 16       |

## Numerics

16-bit/32-bit displacement ..... 57

## A

A/D conversion time  
(multi mode and scan mode)..... 1038  
A/D conversion time (single mode)..... 1037  
A/D conversion timing ..... 1037  
A/D converter (ADC) ..... 1019  
A/D converter activation..... 599  
A/D converter characteristics..... 1605  
A/D converter start request delaying  
function ..... 592  
Absolute address ..... 57  
Absolute address accessing..... 57  
Absolute maximum ratings..... 1521  
AC characteristics..... 1531  
AC characteristics measurement  
conditions..... 1604  
Access size and data alignment ..... 294  
Access wait control..... 306  
ADC timing ..... 1588  
Address array ..... 216, 230  
Address array read ..... 230  
Address errors..... 131  
Address map ..... 240  
Address multiplexing..... 318  
Address spaces of on-chip  
high-speed RAM..... 1393  
Address spaces of on-chip RAM  
for data retention..... 1393  
Address-array write  
(associative operation)..... 231  
Address-array write  
(non-associative operation)..... 230  
Addressing modes..... 58  
Analog input pin ratings ..... 1043

AND/NAND flash memory controller  
(FLCTL)..... 1053  
Arithmetic operation instructions..... 77  
Auto-refreshing ..... 345  
Auto-request mode..... 421

## B

Bank active ..... 338  
Banked register and input/output  
of banks..... 186  
BCHG interrupt..... 1189  
BEMP interrupt..... 1183  
Bit manipulation instructions ..... 88  
Bit synchronous circuit ..... 871  
Branch instructions ..... 82  
BRDY interrupt..... 1176  
Break detection and processing..... 787  
Break on data access cycle..... 208  
Break on instruction fetch cycle..... 207  
Buffer memory ..... 1197  
Bulk transfers ..... 1215  
Burst mode ..... 435  
Burst MPX-I/O interface..... 372  
Burst read ..... 330  
Burst ROM (clocked asynchronous)  
interface ..... 358  
Burst ROM (clocked synchronous)  
interface ..... 377  
Burst write..... 335  
Bus arbitration..... 385  
Bus format for SSI module ..... 892  
Bus state controller (BSC) ..... 235  
Bus timing ..... 1539  
Bus-released state..... 90

## C

Cache ..... 215
