User's Manual: Hardware

Renesas 32-Bit RISC Microcomputer  
SuperH™ RISC engine Family / SH7200 Series

SH7203

R5S72030W200FP

## Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
3. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from such alteration, modification, copy or otherwise misappropriation of Renesas Electronics product.
5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The recommended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.  
"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots etc.  
"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; and safety equipment etc.

Renesas Electronics products are neither intended nor authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems, surgical implantations etc.), or may cause serious property damages (nuclear reactor control systems, military equipment etc.). You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application for which it is not intended. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for which the product is not intended by Renesas Electronics.

6. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
  7. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or systems manufactured by you.
  8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
  9. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You should not use Renesas Electronics products or technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. When exporting the Renesas Electronics products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations.
  10. It is the responsibility of the buyer or distributor of Renesas Electronics products, who distributes, disposes of, or otherwise places the product with a third party, to notify such third party in advance of the contents and conditions set forth in this document. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties as a result of unauthorized use of Renesas Electronics products.
  11. This document may not be reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
  12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.
- (Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.
- (Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

(2012.4)

## General Precautions on Handling of Product

### 1. Treatment of NC Pins

**Note:** Do not connect anything to the NC pins.

The NC (not connected) pins are either not connected to any of the internal circuitry or are they are used as test pins or to reduce noise. If something is connected to the NC pins, the operation of the LSI is not guaranteed.

### 2. Treatment of Unused Input Pins

**Note:** Fix all unused input pins to high or low level.

Generally, the input pins of CMOS products are high-impedance input pins. If unused pins are in their open states, intermediate levels are induced by noise in the vicinity, a pass-through current flows internally, and a malfunction may occur.

### 3. Processing before Initialization

**Note:** When power is first supplied, the product's state is undefined.

The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Design your system so that it does not malfunction because of processing while it is in this undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.

### 4. Prohibition of Access to Undefined or Reserved Addresses

**Note:** Access to undefined or reserved addresses is prohibited.

The undefined or reserved addresses may be used to expand functions, or test registers may have been allocated to these addresses. Do not access these registers; the system's operation is not guaranteed if they are accessed.

### 5. Reading from/Writing to Reserved Bit of Each Register

**Note:** Treat the reserved bit of register used in each module as follows except in cases where the specifications for values which are read from or written to the bit are provided in the description.

The bit is always read as 0. The write value should be 0 or one, which has been read immediately before writing.

Writing the value, which has been read immediately before writing has the advantage of preventing the bit from being affected on its extended function when the function is assigned.

# Configuration of This Manual

This manual comprises the following items:

1. General Precautions in the Handling of MPU/MCU Products
2. Configuration of This Manual
3. Preface
4. Contents
5. Overview
6. Description of Functional Modules

- CPU and System-Control Modules
- On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to the module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each section includes notes in relation to the descriptions given, and usage notes are given, as required, as the final part of each section.

7. List of Registers
8. Electrical Characteristics
9. Appendix
  - Product Type, Package Dimensions, etc.
10. Main Revisions for This Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in this manual.

11. Index

# Preface

This LSI is an RISC (Reduced Instruction Set Computer) microcomputer which includes a Renesas-original RISC CPU as its core, and the peripheral functions required to configure a system.

**Target Users:** This manual was written for users who will be using this LSI in the design of application systems. Target users are expected to understand the fundamentals of electrical circuits, logical circuits, and microcomputers.

**Objective:** This manual was written to explain the hardware functions and electrical characteristics of this LSI to the target users.  
Refer to the SH-2A, SH2A-FPU Software Manual for a detailed description of the instruction set.

Notes on reading this manual:

- In order to understand the overall functions of the chip  
Read the manual according to the contents. This manual can be roughly categorized into parts on the CPU, system control functions, peripheral functions and electrical characteristics.
- In order to understand the details of the CPU's functions  
Read the SH-2A, SH2A-FPU Software Manual.
- In order to understand the details of a register when its name is known  
Read the index that is the final part of the manual to find the page number of the entry on the register. The addresses, bits, and initial values of the registers are summarized in section 34, List of Registers.

- Description of Numbers and Symbols

Aspects of the notations for register names, bit names, numbers, and symbolic names in this manual are explained below.

(1) Overall notation

In descriptions involving the names of bits and bit fields within this manual, the modules and registers to which the bits belong may be clarified by giving the names in the forms "module name", "register name", "bit name" or "register name", "bit name".

(2) Register notation

The style "register name" \_ "instance number" is used in cases where there is more than one instance of the same function or similar functions.

[Example] CMCSR\_0: Indicates the CMCSR register for the compare-match timer of channel 0.

(3) Number notation

Binary numbers are given as B'nnnn (B' may be omitted if the number is obviously binary), hexadecimal numbers are given as H'nnnn or 0xnnnn, and decimal numbers are given as nnnn.

[Examples] Binary: B'11 or 11  
Hexadecimal: H'EFA0 or 0xEFA0  
Decimal: 1234

(4) Notation for active-low

An overbar on the name indicates that a signal or pin is active-low.

[Example] WDTOVF̄

Note: The bit names and sentences in the above figure are examples and do not refer to specific data in this manual.

- Description of Registers

Each register description includes a bit chart, illustrating the arrangement of bits, and a table of bits, describing the meanings of the bit settings. The standard format and notation for bit charts and tables are described below.

[Bit Chart]

|                |     |     |       |       |       |    |   |     |     |     |     |     |       |       |       |     |
|----------------|-----|-----|-------|-------|-------|----|---|-----|-----|-----|-----|-----|-------|-------|-------|-----|
| Bit:           | 15  | 14  | 13    | 12    | 11    | 10 | 9 | 8   | 7   | 6   | 5   | 4   | 3     | 2     | 1     | 0   |
|                | —   | —   | ASID2 | ASID1 | ASID0 | —  | — | —   | —   | —   | —   | Q   | ACMP2 | ACMP1 | ACMP0 | IFE |
| Initial value: | 0   | 0   | 0     | 0     | 0     | 0  | 1 | 0   | 0   | 0   | 0   | 0   | 0     | 0     | 0     | 0   |
| R/W:           | R/W | R/W | R/W   | R/W   | R/W   | R  | R | R/W | R/W | R/W | R/W | R/W | R/W   | R/W   | R/W   | R/W |

[Table of Bits]

| Bit      | Bit Name       | Initial Value | R/W | Description                                                          |
|----------|----------------|---------------|-----|----------------------------------------------------------------------|
| 15       | —              | 0             | R   | Reserved                                                             |
| 14       | —              | 0             | R   | These bits are always read as 0.                                     |
| 13 to 11 | ASID2 to ASID0 | All 0         | R/W | Address Identifier<br>These bits enable or disable the pin function. |
| 10       | —              | 0             | R   | Reserved<br>This bit is always read as 0.                            |
| 9        | —              | 1             | R   | Reserved<br>This bit is always read as 1.                            |
| —        | —              | 0             | —   | —                                                                    |

Note: The bit names and sentences in the above figure are examples, and have nothing to do with the contents of this manual.

(1) Bit

Indicates the bit number or numbers.

In the case of a 32-bit register, the bits are arranged in order from 31 to 0. In the case of a 16-bit register, the bits are arranged in order from 15 to 0.

(2) Bit name

Indicates the name of the bit or bit field.

When the number of bits has to be clearly indicated in the field, appropriate notation is included (e.g., ASID[3:0]).

A reserved bit is indicated by "—".

Certain kinds of bits, such as those of timer counters, are not assigned bit names. In such cases, the entry under Bit Name is blank.

(3) Initial value

Indicates the value of each bit immediately after a power-on reset, i.e., the initial value.

0: The initial value is 0

1: The initial value is 1

—: The initial value is undefined

(4) R/W

For each bit and bit field, this entry indicates whether the bit or field is readable or writable, or both writing to and reading from the bit or field are impossible.

The notation is as follows:

R/W: The bit or field is readable and writable.

R/(W): The bit or field is readable and writable.

However, writing is only performed to flag clearing.

R: The bit or field is readable.

"R" is indicated for all reserved bits. When writing to the register, write the value under Initial Value in the bit chart to reserved bits or fields.

W: The bit or field is writable.

(5) Description

Describes the function of the bit or field and specifies the values for writing.

All trademarks and registered trademarks are the property of their respective owners.

# Section 1 Overview

## 1.1 SH7203 Features

This LSI is a single-chip RISC (reduced instruction set computer) microcontroller that includes a Renesas-original RISC CPU as its core, and the peripheral functions required to configure a system.

The CPU in this LSI is the SH-2A CPU that provides upward compatibility for SH-1, SH-2, and SH-2E CPUs at object code level. It has a RISC-type instruction set and uses a superscalar architecture and a Harvard architecture, which greatly improves instruction execution speed. In addition, the 32-bit internal-bus architecture that is independent from the direct memory access controller (DMAC) enhances data processing power. This CPU brings the user the ability to set up high-performance systems with strong functionality at less expense than was achievable with previous microcontrollers, and is even able to handle realtime control applications requiring high-speed characteristics.

This LSI has a floating-point unit (FPU) and cache. In addition, this LSI includes on-chip peripheral functions necessary for system configuration, such as 64-Kbyte RAM for high-speed operation, 16-Kbyte RAM for data retention, a multi-function timer pulse unit 2 (MTU2), a compare match timer (CMT), a realtime clock (RTC), a serial communication interface with FIFO (SCIF), a synchronous serial communication unit (SSU), an I<sup>2</sup>C bus interface 3 (IIC3), a serial sound interface (SSI), a controller area network (RCAN-TL1), an A/D converter, a D/A converter, an AND/NAND flash memory controller (FLCTL), a USB2.0 host/function module (USB), an interrupt controller (INTC), and I/O ports.

This LSI also provides an external memory access support function to enable direct connection to various memory devices or peripheral LSIs. These on-chip functions significantly reduce costs of designing and manufacturing application systems. Furthermore, I/O pins in this LSI have weak keeper circuits that prevent the pin voltage from entering an intermediate potential range. Therefore, no external circuits to fix the input level are required, which reduces the parts number considerably.

The features of this LSI are listed in table 1.1.

**Table 1.1 SH7203 Features**

| Items | Specification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Section 2 CPU

### 2.1 Register Configuration

The register set consists of sixteen 32-bit general registers, four 32-bit control registers, and four 32-bit system registers.

#### 2.1.1 General Registers

Figure 2.1 shows the general registers.

The sixteen 32-bit general registers are numbered R0 to R15. General registers are used for data processing and address calculation. R0 is also used as an index register. Several instructions have R0 fixed as their only usable register. R15 is used as the hardware stack pointer (SP). Saving and restoring the status register (SR) and program counter (PC) in exception handling is accomplished by referencing the stack using R15.

- Notes:
1. R0 functions as an index register in the indexed register indirect addressing mode and indexed GBR indirect addressing mode. In some instructions, R0 functions as a fixed source register or destination register.
  2. R15 functions as a hardware stack pointer (SP) during exception processing.

**Figure 2.1 General Registers**

## 2.1.2 Control Registers

The control registers consist of four 32-bit registers: the status register (SR), the global base register (GBR), the vector base register (VBR), and the jump table base register (TBR).

The status register indicates instruction processing states.

The global base register functions as a base address for the GBR indirect addressing mode to transfer data to the registers of on-chip peripheral modules.

The vector base register functions as the base address of the exception handling vector area (including interrupts).

The jump table base register functions as the base address of the function table area.

**Figure 2.2 Control Registers**

### (1) Status Register (SR)

| 9        | M        | —             | R/W | M Bit                                                                                                                                                              |
| 8        | Q        | —             | R/W | Q Bit<br>Used by the DIV0S, DIV0U, and DIV1 instructions.                                                                                                          |
| 7 to 4   | I[3:0]   | 1111          | R/W | Interrupt Mask Level                                                                                                                                               |
| 3, 2     | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                   |
| 1        | S        | —             | R/W | S Bit<br>Specifies a saturation operation for a MAC instruction.                                                                                                   |
| 0        | T        | —             | R/W | T Bit<br>True/false condition or carry/borrow bit                                                                                                                  |

## (2) Global Base Register (GBR)

GBR is referenced as the base address in a GBR-referencing MOV instruction.

## (3) Vector Base Register (VBR)

VBR is referenced as the branch destination base address in the event of an exception or an interrupt.

## (4) Jump Table Base Register (TBR)

TBR is referenced as the start address of a function table located in memory in a JSR/N@@(disp8,TBR) table-referencing subroutine call instruction.

### 2.1.3 System Registers

The system registers consist of four 32-bit registers: the high and low multiply and accumulate registers (MACH and MACL), the procedure register (PR), and the program counter (PC). MACH and MACL store the results of multiply or multiply and accumulate operations. PR stores the return address from a subroutine procedure. PC indicates the address four bytes ahead of the instruction being executed and controls the flow of the processing.

**Figure 2.3 System Registers**

#### (1) Multiply and Accumulate Register High (MACH) and Multiply and Accumulate Register Low (MACL)

MACH and MACL are used as the addition value in a MAC instruction, and store the result of a MAC or MUL instruction.

#### (2) Procedure Register (PR)

PR stores the return address of a subroutine call using a BSR, BSRF, or JSR instruction, and is referenced by a subroutine return instruction (RTS).

#### (3) Program Counter (PC)

PC indicates the address four bytes ahead of the instruction being executed.

### 2.1.4 Register Banks

For the nineteen 32-bit registers comprising general registers R0 to R14, control register GBR, and system registers MACH, MACL, and PR, high-speed register saving and restoration can be carried out using a register bank. The register contents are automatically saved in the bank after the CPU accepts an interrupt that uses a register bank. Restoration from the bank is executed by issuing a RESBANK instruction in an interrupt processing routine.

This LSI has 15 banks. For details, see the SH-2A, SH2A-FPU Software Manual and section 6.8, Register Banks.

### 2.1.5 Initial Values of Registers

Table 2.1 lists the values of the registers after a reset.

**Table 2.1 Initial Values of Registers**

| Classification    | Register       | Initial Value                                                                                  |
|-------------------|----------------|------------------------------------------------------------------------------------------------|
| General registers | R0 to R14      | Undefined                                                                                      |
|                   | R15 (SP)       | Value of the stack pointer in the vector address table                                         |
| Control registers | SR             | Bits I[3:0] are 1111 (H'F), BO and CS are 0, reserved bits are 0, and other bits are undefined |
|                   | GBR, TBR       | Undefined                                                                                      |
|                   | VBR            | H'00000000                                                                                     |
| System registers  | MACH, MACL, PR | Undefined                                                                                      |
|                   | PC             | Value of the program counter in the vector address table                                       |

## 2.2 Data Formats

### 2.2.1 Data Format in Registers

Register operands are always longwords (32 bits). If the size of memory operand is a byte (8 bits) or a word (16 bits), it is changed into a longword by expanding the sign-part when loaded into a register.

**Figure 2.4 Data Format in Registers**

### 2.2.2 Data Formats in Memory

Memory data formats are classified into bytes, words, and longwords. Memory can be accessed in 8-bit bytes, 16-bit words, or 32-bit longwords. A memory operand of fewer than 32 bits is stored in a register in sign-extended or zero-extended form.

A word operand should be accessed at a word boundary (an even address of multiple of two bytes: address  $2n$ ), and a longword operand at a longword boundary (an even address of multiple of four bytes: address  $4n$ ). Otherwise, an address error will occur. A byte operand can be accessed at any address.

Only big-endian byte order can be selected for the data format.

Data formats in memory are shown in figure 2.5.

**Figure 2.5 Data Formats in Memory**

### 2.2.3 Immediate Data Format

Byte (8-bit) immediate data is located in an instruction code. Immediate data accessed by the MOV, ADD, and CMP/EQ instructions is sign-extended and handled in registers as longword data. Immediate data accessed by the TST, AND, OR, and XOR instructions is zero-extended and handled as longword data. Consequently, AND instructions with immediate data always clear the upper 24 bits of the destination register.

20-bit immediate data is located in the code of a MOVI20 or MOVI20S 32-bit transfer instruction. The MOVI20 instruction stores immediate data in the destination register in sign-extended form. The MOVI20S instruction shifts immediate data by eight bits in the upper direction, and stores it in the destination register in sign-extended form.

Word or longword immediate data is not located in the instruction code, but rather is stored in a memory table. The memory table is accessed by an immediate data transfer instruction (MOV) using the PC relative addressing mode with displacement.

See examples given in section 2.3.1 (10), Immediate Data.

## 2.3 Instruction Features

### 2.3.1 RISC-Type Instruction Set

Instructions are RISC type. This section details their functions.

#### (1) 16-Bit Fixed-Length Instructions

Basic instructions have a fixed length of 16 bits, improving program code efficiency.

#### (2) 32-Bit Fixed-Length Instructions

The SH-2A additionally features 32-bit fixed-length instructions, improving performance and ease of use.

#### (3) One Instruction per State

Each basic instruction can be executed in one cycle using the pipeline system.

#### (4) Data Length

Longword is the standard data length for all operations. Memory can be accessed in bytes, words, or longwords. Byte or word data in memory is sign-extended and handled as longword data. Immediate data is sign-extended for arithmetic operations or zero-extended for logic operations. It is also handled as longword data.

**Table 2.2 Sign Extension of Word Data**

| SH2-A CPU |                 | Description                                                                                                  | Example of Other CPU |
|-----------|-----------------|--------------------------------------------------------------------------------------------------------------|----------------------|
| MOV.W     | @(disp, PC), R1 | Data is sign-extended to 32 bits, and R1 becomes H'00001234. It is next operated upon by an ADD instruction. | ADD.W #H'1234, R0    |
| ADD       | R1, R0          |                                                                                                              |                      |
|           | .....           |                                                                                                              |                      |
| .DATA.W   | H'1234          |                                                                                                              |                      |

Note: @(disp, PC) accesses the immediate data.

#### (5) Load-Store Architecture

Basic operations are executed between registers. For operations that involve memory access, data is loaded to the registers and executed (load-store architecture). Instructions such as AND that manipulate bits, however, are executed directly in memory.

## (6) Delayed Branch Instructions

With the exception of some instructions, unconditional branch instructions, etc., are executed as delayed branch instructions. With a delayed branch instruction, the branch is taken after execution of the instruction immediately following the delayed branch instruction. This reduces disturbance of the pipeline control when a branch is taken.

In a delayed branch, the actual branch operation occurs after execution of the slot instruction. However, instruction execution such as register updating excluding the actual branch operation, is performed in the order of delayed branch instruction → delay slot instruction. For example, even though the contents of the register holding the branch destination address are changed in the delay slot, the branch destination address remains as the register contents prior to the change.

**Table 2.3 Delayed Branch Instructions**

| SH-2A CPU |        | Description                                 | Example of Other CPU |        |
|-----------|--------|---------------------------------------------|----------------------|--------|
| BRA       | TRGET  | Executes the ADD before branching to TRGET. | ADD.W                | R1, R0 |
| ADD       | R1, R0 |                                             | BRA                  | TRGET  |

## (7) Unconditional Branch Instructions with No Delay Slot

The SH-2A additionally features unconditional branch instructions in which a delay slot instruction is not executed. This eliminates unnecessary NOP instructions, and so reduces the code size.

## (8) Multiply/Multiply-and-Accumulate Operations

16-bit × 16-bit → 32-bit multiply operations are executed in one to two cycles. 16-bit × 16-bit + 64-bit → 64-bit multiply-and-accumulate operations are executed in two to three cycles. 32-bit × 32-bit → 64-bit multiply and 32-bit × 32-bit + 64-bit → 64-bit multiply-and-accumulate operations are executed in two to four cycles.

## (9) T Bit

The T bit in the status register (SR) changes according to the result of the comparison. Whether a conditional branch is taken or not taken depends upon the T bit condition (true/false). The number of instructions that change the T bit is kept to a minimum to improve the processing speed.

Table 2.4 T Bit

| SH-2A CPU |         | Description                                                                     | Example of Other CPU |        |
|-----------|---------|---------------------------------------------------------------------------------|----------------------|--------|
| CMP/GE    | R1, R0  | T bit is set when $R0 \geq R1$ .                                                | CMP.W                | R1, R0 |
| BT        | TRGET0  | The program branches to TRGET0 when $R0 \geq R1$ and to TRGET1 when $R0 < R1$ . | BGE                  | TRGET0 |
| BF        | TRGET1  |                                                                                 | BLT                  | TRGET1 |
| ADD       | #-1, R0 | T bit is not changed by ADD.                                                    | SUB.W                | #1, R0 |
| CMP/EQ    | #0, R0  | T bit is set when $R0 = 0$ .                                                    | BEQ                  | TRGET  |
| BT        | TRGET   | The program branches if $R0 = 0$ .                                              |                      |        |

(10) Immediate Data

Byte immediate data is located in an instruction code. Word or longword immediate data is not located in instruction codes but in a memory table. The memory table is accessed by an immediate data transfer instruction (MOV) using the PC relative addressing mode with displacement.

With the SH-2A, 17- to 28-bit immediate data can be located in an instruction code. However, for 21- to 28-bit immediate data, an OR instruction must be executed after the data is transferred to a register.

Table 2.5 Immediate Data Accessing

| Classification   | SH-2A CPU |                 | Example of Other CPU |                 |
|------------------|-----------|-----------------|----------------------|-----------------|
| 8-bit immediate  | MOV       | #H'12, R0       | MOV.B                | #H'12, R0       |
| 16-bit immediate | MOVI20    | #H'1234, R0     | MOV.W                | #H'1234, R0     |
| 20-bit immediate | MOVI20    | #H'12345, R0    | MOV.L                | #H'12345, R0    |
| 28-bit immediate | MOVI20S   | #H'12345, R0    | MOV.L                | #H'1234567, R0  |
|                  | OR        | #H'67, R0       |                      |                 |
| 32-bit immediate | MOV.L     | @(disp, PC), R0 | MOV.L                | #H'12345678, R0 |
|                  |           | .....           |                      |                 |
|                  | .DATA.L   | H'12345678      |                      |                 |

Note: @(disp, PC) accesses the immediate data.

(11) Absolute Address

When data is accessed by an absolute address, the absolute address value should be placed in the memory table in advance. That value is transferred to the register by loading the immediate data during the execution of the instruction, and the data is accessed in register indirect addressing mode.

With the SH-2A, when data is referenced using an absolute address not exceeding 28 bits, it is also possible to transfer immediate data located in the instruction code to a register and to reference the data in register indirect addressing mode. However, when referencing data using an absolute address of 21 to 28 bits, an OR instruction must be used after the data is transferred to a register.

Table 2.6 Absolute Address Accessing

| Classification  | SH-2A CPU |               | Example of Other CPU |
|-----------------|-----------|---------------|----------------------|
| Up to 20 bits   | MOVI20    | #H'12345,R1   | MOV.B @H'12345,R0    |
|                 | MOV.B     | @R1,R0        |                      |
| 21 to 28 bits   | MOVI20S   | #H'12345,R1   | MOV.B @H'1234567,R0  |
|                 | OR        | #H'67,R1      |                      |
|                 | MOV.B     | @R1,R0        |                      |
|                 |           | .....         |                      |
| 29 bits or more | MOV.L     | @(disp,PC),R1 | MOV.B @H'12345678,R0 |
|                 | MOV.B     | @R1,R0        |                      |
|                 |           | .....         |                      |
|                 | .DATA.L   | H'12345678    |                      |

(12) 16-Bit/32-Bit Displacement

When data is accessed by 16-bit or 32-bit displacement, the displacement value should be placed in the memory table in advance. That value is transferred to the register by loading the immediate data during the execution of the instruction, and the data is accessed in the indexed indirect register addressing mode.

Table 2.7 Displacement Accessing

| Classification      | SH-2A CPU |               | Example of Other CPU  |
|---------------------|-----------|---------------|-----------------------|
| 16-bit displacement | MOV.W     | @(disp,PC),R0 | MOV.W @(H'1234,R1),R2 |
|                     | MOV.W     | @(R0,R1),R2   |                       |
|                     |           | .....         |                       |
|                     | .DATA.W   | H'1234        |                       |

2.3.2 Addressing Modes

Addressing modes and effective address calculation are as follows:

Table 2.8 Addressing Modes and Effective Addresses

| Addressing Mode                       | Instruction Format | Effective Address Calculation                                                                                                                                                                                                                                                                                    | Equation                                                                                                                             |
|---------------------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| Register direct                       | Rn                 | The effective address is register Rn. (The operand is the contents of register Rn.)                                                                                                                                                                                                                              | —                                                                                                                                    |
| Register indirect                     | @Rn                | The effective address is the contents of register Rn.<br>                                                                                                                                                                       | Rn                                                                                                                                   |
| Register indirect with post-increment | @Rn+               | The effective address is the contents of register Rn. A constant is added to the contents of Rn after the instruction is executed. 1 is added for a byte operation, 2 for a word operation, and 4 for a longword operation.<br> | Rn<br>(After instruction execution)<br>Byte:<br>Rn + 1 → Rn<br>Word:<br>Rn + 2 → Rn<br>Longword:<br>Rn + 4 → Rn                      |
| Register indirect with pre-decrement  | @-Rn               | The effective address is the value obtained by subtracting a constant from Rn. 1 is subtracted for a byte operation, 2 for a word operation, and 4 for a longword operation.<br>                                               | Byte:<br>Rn - 1 → Rn<br>Word:<br>Rn - 2 → Rn<br>Longword:<br>Rn - 4 → Rn<br>(Instruction is executed with Rn after this calculation) |

|                 | #imm:3             | The 3-bit immediate data (imm) for the BAND, BOR, BXOR, BST, BLD, BSET, and BCLR instructions indicates the target bit location.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | —        |

### 2.3.3 Instruction Format

The instruction formats and the meaning of source and destination operands are described below. The meaning of the operand depends on the instruction code. The symbols used are as follows:

- xxxx: Instruction code
- mmmm: Source register
- nnnn: Destination register
- iiii: Immediate data
- dddd: Displacement

**Table 2.9 Instruction Formats**

| Instruction Formats                                                                                 | Source Operand                              | Destination Operand                           | Example           |
|-----------------------------------------------------------------------------------------------------|---------------------------------------------|-----------------------------------------------|-------------------|
| <b>0 format</b><br> | —                                           | —                                             | NOP               |

Note: \* In multiply-and-accumulate instructions, nnnn is the source register.

## 2.4 Instruction Set

### 2.4.1 Instruction Set by Classification

Table 2.10 lists the instructions according to their classification.

**Table 2.10 Classification of Instructions**

| Classification | Types | Operation Code | Function                                                                                                                         | No. of Instructions |
|----------------|-------|----------------|----------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Data transfer  | 13    | MOV            | Data transfer<br>Immediate data transfer<br>Peripheral module data transfer<br>Structure data transfer<br>Reverse stack transfer | 62                  |
|                |       | MOVA           | Effective address transfer                                                                                                       |                     |
|                |       | MOVI20         | 20-bit immediate data transfer                                                                                                   |                     |
|                |       | MOVI20S        | 20-bit immediate data transfer<br>8-bit left-shift                                                                               |                     |

The table below shows the format of instruction codes, operation, and execution states. They are described by using this format according to their classification.

| Instruction                      | Instruction Code              | Operation                           | Execution States                                      | T Bit                                         |
|----------------------------------|-------------------------------|-------------------------------------|-------------------------------------------------------|-----------------------------------------------|
| Indicated by mnemonic.           | Indicated in MSB ↔ LSB order. | Indicates summary of operation.     | Value when no wait states are inserted.* <sup>1</sup> | Value of T bit after instruction is executed. |
| [Legend]                         | [Legend]                      | [Legend]                            |                                                       | Explanation of Symbols                        |
| Rm: Source register              | mmmm: Source register         | →, ←: Transfer direction            |                                                       | —: No change                                  |
| Rn: Destination register         | nnnn: Destination register    | (xx): Memory operand                |                                                       |                                               |

|                                  | dddd: Displacement            | <<n: n-bit left shift               |                                                       |                                               |
|                                  |                               | >>n: n-bit right shift              |                                                       |                                               |

Notes: 1. Instruction execution cycles: The execution cycles shown in the table are minimums. In practice, the number of instruction execution states will be increased in cases such as the following:

- When there is a conflict between an instruction fetch and a data access
  - When the destination register of a load instruction (memory → register) is the same as the register used by the next instruction.
2. Depending on the operand size, displacement is scaled by ×1, ×2, or ×4. For details, refer to the SH-2A, SH2A-FPU Software Manual.

## 2.4.2 Data Transfer Instructions

Notes: 1. Instruction execution cycles: The execution cycles shown in the table are minimums. In practice, the number of instruction execution states in cases such as the following:

- When there is a conflict between an instruction fetch and a data access
- When the destination register of a load instruction (memory → register) is the same as the register used by the next instruction.

\* In the event of bank overflow, the number of cycles is 19.

## 2.4.8 Floating-Point Operation Instructions

**Table 2.17 Floating-Point Operation Instructions**

| Instruction |               | Instruction Code   | Operation             | Execution Cycles | T Bit             | Compatibility |     |                    |

## 2.5 Processing States

The CPU has five processing states: reset, exception handling, bus-released, program execution, and power-down. Figure 2.6 shows the transitions between the states.

**Figure 2.6 Transitions between Processing States**

### (1) Reset State

In the reset state, the CPU is reset. There are two kinds of reset, power-on reset and manual reset.

### (2) Exception Handling State

The exception handling state is a transient state that occurs when exception handling sources such as resets or interrupts alter the CPU's processing state flow.

For a reset, the initial values of the program counter (PC) (execution start address) and stack pointer (SP) are fetched from the exception handling vector table and stored; the CPU then branches to the execution start address and execution of the program begins.

For an interrupt, the stack pointer (SP) is accessed and the program counter (PC) and status register (SR) are saved to the stack area. The exception service routine start address is fetched from the exception handling vector table; the CPU then branches to that address and the program starts executing, thereby entering the program execution state.

### (3) Program Execution State

In the program execution state, the CPU sequentially executes the program.

### (4) Power-Down State

In the power-down state, the CPU stops operating to reduce power consumption. The SLEEP instruction places the CPU in sleep mode, software standby mode, or deep standby mode.

### (5) Bus-Released State

In the bus-released state, the CPU releases bus to a device that has requested it.

## Section 3 Floating-Point Unit (FPU)

### 3.1 Features

The FPU has the following features.

- Conforms to IEEE754 standard
- 16 single-precision floating-point registers (can also be referenced as eight double-precision registers)
- Two rounding modes: Round to nearest and round to zero
- Denormalization modes: Flush to zero
- Five exception sources: Invalid operation, divide by zero, overflow, underflow, and inexact
- Comprehensive instructions: Single-precision, double-precision, and system control

3.2 Data Formats

3.2.1 Floating-Point Format

A floating-point number consists of the following three fields:

- Sign (s)
- Exponent (e)
- Fraction (f)

This LSI can handle single-precision and double-precision floating-point numbers, using the formats shown in figures 3.1 and 3.2.

Figure 3.1 Format of Single-Precision Floating-Point Number

Figure 3.2 Format of Double-Precision Floating-Point Number

The exponent is expressed in biased form, as follows:

$$e = E + \text{bias}$$

The range of unbiased exponent E is  $E_{\min} - 1$  to  $E_{\max} + 1$ . The two values  $E_{\min} - 1$  and  $E_{\max} + 1$  are distinguished as follows.  $E_{\min} - 1$  indicates zero (both positive and negative sign) and a denormalized number, and  $E_{\max} + 1$  indicates positive or negative infinity or a non-number (NaN). Table 3.1 shows  $E_{\min}$  and  $E_{\max}$  values.

**Table 3.1 Floating-Point Number Formats and Parameters**

| Parameter       | Single-Precision | Double-Precision |
|-----------------|------------------|------------------|
| Total bit width | 32 bits          | 64 bits          |
| Sign bit        | 1 bit            | 1 bit            |
| Exponent field  | 8 bits           | 11 bits          |
| Fraction field  | 23 bits          | 52 bits          |
| Precision       | 24 bits          | 53 bits          |
| Bias            | +127             | +1023            |
| $E_{\max}$      | +127             | +1023            |
| $E_{\min}$      | -126             | -1022            |

Floating-point number value  $v$  is determined as follows:

- If  $E = E_{\max} + 1$  and  $f \neq 0$ ,  $v$  is a non-number (NaN) irrespective of sign  $s$
- If  $E = E_{\max} + 1$  and  $f = 0$ ,  $v = (-1)^s$  (infinity) [positive or negative infinity]
- If  $E_{\min} \leq E \leq E_{\max}$ ,  $v = (-1)^s 2^E (1.f)$  [normalized number]
- If  $E = E_{\min} - 1$  and  $f \neq 0$ ,  $v = (-1)^s 2^{E_{\min}} (0.f)$  [denormalized number]
- If  $E = E_{\min} - 1$  and  $f = 0$ ,  $v = (-1)^s 0$  [positive or negative zero]

Table 3.2 shows the ranges of the various numbers in hexadecimal notation.

**Table 3.2 Floating-Point Ranges**

| Type                         | Single-Precision           | Double-Precision                               |
|------------------------------|----------------------------|------------------------------------------------|
| Signaling non-number         | H'7FFF FFFF to H'7FC0 0000 | H'7FFF FFFF FFFF FFFF to H'7FF8 0000 0000 0000 |
| Quiet non-number             | H'7FBF FFFF to H'7F80 0001 | H'7FF7 FFFF FFFF FFFF to H'7FF0 0000 0000 0001 |
| Positive infinity            | H'7F80 0000                | H'7FF0 0000 0000 0000                          |
| Positive normalized number   | H'7F7F FFFF to H'0080 0000 | H'7FEF FFFF FFFF FFFF to H'0010 0000 0000 0000 |
| Positive denormalized number | H'007F FFFF to H'0000 0001 | H'000F FFFF FFFF FFFF to H'0000 0000 0000 0001 |
| Positive zero                | H'0000 0000                | H'0000 0000 0000 0000                          |
| Negative zero                | H'8000 0000                | H'8000 0000 0000 0000                          |
| Negative denormalized number | H'8000 0001 to H'807F FFFF | H'8000 0000 0000 0001 to H'800F FFFF FFFF FFFF |
| Negative normalized number   | H'8080 0000 to H'FF7F FFFF | H'8010 0000 0000 0000 to H'FFEF FFFF FFFF FFFF |
| Negative infinity            | H'FF80 0000                | H'FFF0 0000 0000 0000                          |
| Quiet non-number             | H'FF80 0001 to H'FFBF FFFF | H'FFF0 0000 0000 0001 to H'FFF7 FFFF FFFF FFFF |
| Signaling non-number         | H'FFC0 0000 to H'FFFF FFFF | H'FFF8 0000 0000 0000 to H'FFFF FFFF FFFF FFFF |

3.2.2 Non-Numbers (NaN)

Figure 3.3 shows the bit pattern of a non-number (NaN). A value is NaN in the following case:

- Sign bit: Don't care
- Exponent field: All bits are 1
- Fraction field: At least one bit is 1

The NaN is a signaling NaN (sNaN) if the MSB of the fraction field is 1, and a quiet NaN (qNaN) if the MSB is 0.

Figure 3.3 Single-Precision NaN Bit Pattern

An sNaN is input in an operation, except copy, FABS, and FNEG, that generates a floating-point value.

- When the EN.V bit in FPSCR is 0, the operation result (output) is a qNaN.
- When the value of the EN.V bit in FPSCR is 1, FPU exception handling is triggered by an invalid operation exception. In this case, the contents of the operation destination register are unchanged.

If a qNaN is input in an operation that generates a floating-point value, and an sNaN has not been input in that operation, the output will always be a qNaN irrespective of the setting of the EN.V bit in FPSCR. An exception will not be generated in this case.

The qNaN values as operation results are as follows:

- Single-precision qNaN: H'7FBF FFFF
- Double-precision qNaN: H'7FF7 FFFF FFFF FFFF

See the individual instruction descriptions for details of floating-point operations when a non-number (NaN) is input.

### 3.2.3 Denormalized Numbers

For a denormalized number floating-point value, the exponent field is expressed as 0, and the fraction field as a non-zero value.

In the SH2A-FPU, the DN bit in the status register FPSCR is always set to 1, therefore a denormalized number (source operand or operation result) is always flushed to 0 in a floating-point operation that generates a value (an operation other than copy, FNEG, or FABS).

When the DN bit in FPSCR is 0, a denormalized number (source operand or operation result) is processed as it is. See the individual instruction descriptions for details of floating-point operations when a denormalized number is input.

### 3.3 Register Descriptions

#### 3.3.1 Floating-Point Registers

Figure 3.4 shows the floating-point register configuration. There are sixteen 32-bit floating-point registers FPR0 to FPR15, referenced by specifying FR0 to FR15, DR0/2/4/6/8/10/12/14. The correspondence between FRPn and the reference name is determined by the PR and SZ bits in FPSCR. Refer figure 3.4.

1. Floating-point registers, FPRi (16 registers)  
FPR0 to FPR15
2. Single-precision floating-point registers, FRi (16 registers)  
FR0 to FR15 indicate FPR0 to FPR15
3. Double-precision floating-point registers or single-precision floating-point vector registers in pairs, DRi (8 registers)  
A DR register comprises two FR registers.  
DR0 = {FR0, FR1}, DR2 = {FR2, FR3}, DR4 = {FR4, FR5}, DR6 = {FR6, FR7},  
DR8 = {FR8, FR9}, DR10 = {FR10, FR11}, DR12 = {FR12, FR13}, DR14 = {FR14, FR15}

Figure 3.4 Floating-Point Registers

### 3.3.2 Floating-Point Status/Control Register (FPSCR)

FPSCR is a 32-bit register that controls floating-point instructions, sets FPU exceptions, and selects the rounding mode.

**Table 3.3 Bit Allocation for FPU Exception Handling**

| Field Name |                            | FPU Error (E) | Invalid Operation (V) | Division by Zero (Z) | Overflow (O) | Underflow (U) | Inexact (I) |
|------------|----------------------------|---------------|-----------------------|----------------------|--------------|---------------|-------------|
| Cause      | FPU exception cause field  | Bit 17        | Bit 16                | Bit 15               | Bit 14       | Bit 13        | Bit 12      |
| Enable     | FPU exception enable field | None          | Bit 11                | Bit 10               | Bit 9        | Bit 8         | Bit 7       |
| Flag       | FPU exception flag field   | None          | Bit 6                 | Bit 5                | Bit 4        | Bit 3         | Bit 2       |

Note: No FPU error occurs in the SH2A-FPU.

### 3.3.3 Floating-Point Communication Register (FPUL)

Information is transferred between the FPU and CPU via FPUL. FPUL is a 32-bit system register that is accessed from the CPU side by means of LDS and STS instructions. For example, to convert the integer stored in general register R1 to a single-precision floating-point number, the processing flow is as follows:

R1 → (LDS instruction) → FPUL → (single-precision FLOAT instruction) → FR1

## 3.4 Rounding

In a floating-point instruction, rounding is performed when generating the final operation result from the intermediate result. Therefore, the result of combination instructions such as FMAC will differ from the result when using a basic instruction such as FADD, FSUB, or FMUL. Rounding is performed once in FMAC, but twice in FADD, FSUB, and FMUL.

Which of the two rounding methods is to be used is determined by the RM bits in FPSCR.

FPSCR.RM[1:0] = 00: Round to Nearest

FPSCR.RM[1:0] = 01: Round to Zero

### (1) Round to Nearest

The operation result is rounded to the nearest expressible value. If there are two nearest expressible values, the one with an LSB of 0 is selected.

If the unrounded value is  $2^{E_{\max}}$  ( $2 - 2^{-P}$ ) or more, the result will be infinity with the same sign as the unrounded value. The values of Emax and P, respectively, are 127 and 24 for single-precision, and 1023 and 53 for double-precision.

### (2) Round to Zero

The digits below the round bit of the unrounded value are discarded.

If the unrounded value is larger than the maximum expressible absolute value, the value will become the maximum expressible absolute value.

## 3.5 FPU Exceptions

### 3.5.1 FPU Exception Sources

FPU exceptions may be triggered by floating point operation instructions. The exception sources are as follows:

- FPU error (E): When  $\text{FPSCR.DN} = 0$  and a denormalized number is input (No error occurs in the SH2A-FPU)
- Invalid operation (V): In case of an invalid operation, such as NaN input
- Division by zero (Z): Division with a zero divisor
- Overflow (O): When the operation result overflows
- Underflow (U): When the operation result underflows
- Inexact exception (I): When overflow, underflow, or rounding occurs

The FPU exception cause field in FPSCR contains bits corresponding to all of above sources E, V, Z, O, U, and I, and the FPU exception flag and enable fields in FPSCR contain bits corresponding to sources V, Z, O, U, and I, but not E. Thus, FPU errors cannot be disabled.

When an FPU exception occurs, the corresponding bit in the FPU exception cause field is set to 1, and 1 is added to the corresponding bit in the FPU exception flag field. When an FPU exception does not occur, the corresponding bit in the FPU exception cause field is cleared to 0, but the corresponding bit in the FPU exception flag field remains unchanged.

### 3.5.2 FPU Exception Handling

FPU exception handling is initiated in the following cases:

- FPU error (E):  $\text{FPSCR.DN} = 0$  and a denormalized number is input (No error occurs in the SH2A-FPU)
- Invalid operation (V):  $\text{FPSCR.Enable.V} = 1$  and invalid operation
- Division by zero (Z):  $\text{FPSCR.Enable.Z} = 1$  and division with a zero divisor
- Overflow (O):  $\text{FPSCR.Enable.O} = 1$  and instruction with possibility of operation result overflow
- Underflow (U):  $\text{FPSCR.Enable.U} = 1$  and instruction with possibility of operation result underflow
- Inexact exception (I):  $\text{FPSCR.Enable.I} = 1$  and instruction with possibility of inexact operation result

The possibilities for exception handling caused by floating point operations are described in the individual instruction descriptions. All exception events that originate in floating point operations are assigned as the same FPU exception handling event. The meaning of an exception caused by a floating point operation is determined by software by reading from FPSCR and interpreting the information it contains. Also, the destination register is not changed when FPU exception handling occurs.

Except for the above, the bit corresponding to source V, Z, O, U, or I is set to 1, and a default value is generated as the operation result.

- Invalid operation (V): qNaN is generated as the result.
- Division by zero (Z): Infinity with the same sign as the unrounded value is generated.
- Overflow (O):  
When rounding mode = RZ, the maximum normalized number, with the same sign as the unrounded value, is generated.  
When rounding mode = RN, infinity with the same sign as the unrounded value is generated.
- Underflow (U):  
Zero with the same sign as the unrounded value is generated.
- Inexact exception (I): An inexact result is generated.

## Section 4 Clock Pulse Generator (CPG)

This LSI has a clock pulse generator (CPG) that generates a CPU clock ( $I\phi$ ), a peripheral clock ( $P\phi$ ), and a bus clock ( $B\phi$ ). The CPG consists of a crystal oscillator, PLL circuits, and divider circuits.

### 4.1 Features

- Four clock operating modes

The mode is selected from among the four clock operating modes based on the frequency range to be used and the input clock type: the clock from crystal resonator, the external clock or the clock for USB.

- Three clocks generated independently

A CPU clock ( $I\phi$ ) for the CPU and cache; a peripheral clock ( $P\phi$ ) for the on-chip peripheral modules; a bus clock ( $B\phi = CKIO$ ) for the external bus interface

- Frequency change function

CPU clock and peripheral clock frequencies can be changed independently using the PLL (phase locked loop) circuits and divider circuits within the CPG. Frequencies are changed by software using frequency control register (FRQCR) settings.

- Power-down mode control

The clock can be stopped in sleep mode, software standby mode, and deep standby mode, and specific modules can be stopped using the module standby function. For details on clock control in the power-down modes, see section 28, Power-Down Modes.

Figure 4.1 shows a block diagram of the clock pulse generator.

**Figure 4.1 Block Diagram of Clock Pulse Generator**

The clock pulse generator blocks function as follows:

### **(1) Crystal Oscillator**

The crystal oscillator is used in which the crystal resonator is connected to the XTAL/EXTAL pin or USB\_X1/USB\_X2 pin. One of them is selected according to the clock operating mode.

### **(2) Divider 1**

Divider 1 divides the output from the crystal oscillator or the external clock input. The division ratio depends on the clock operating mode.

### **(3) PLL Circuit**

PLL circuit multiplies the frequency of the output from the divider 1. The multiplication ratio is set by the frequency control register.

### **(4) Divider 2**

Divider 2 generates a clock signal whose operating frequency can be used for the CPU clock, the peripheral clock, and the bus clock. The division ratio of the CPU clock and peripheral clock are set by the frequency control register. The division ratio of the bus clock is determined by the clock operating mode and the PLL multiplication ratio.

### **(5) Clock Frequency Control Circuit**

The clock frequency control circuit controls the clock frequency using the MD\_CLK0 and MD\_CLK1 pins and the frequency control register (FRQCR).

### **(6) Standby Control Circuit**

The standby control circuit controls the states of the clock pulse generator and other modules during clock switching, or sleep, software standby or deep standby mode.

In addition, the standby control register is provided to control the power-down mode of other modules. For details on the standby control register, see section 28, Power-Down Modes.

### **(7) Frequency Control Register (FRQCR)**

The frequency control register (FRQCR) has control bits assigned for the following functions: clock output/non-output from the CKIO pin during software standby mode, the frequency multiplication ratio of PLL circuit, and the frequency division ratio of the CPU clock and the peripheral clock ( $P\phi$ ).

## 4.2 Input/Output Pins

Table 4.1 lists the clock pulse generator pins and their functions.

**Table 4.1 Pin Configuration and Functions of the Clock Pulse Generator**

| Pin Name                                                            | Symbol      | I/O    | Function<br>(Clock Operating<br>Mode 0, 1)                                                                                                                                                                                                                        | Function<br>(Clock Operating<br>Mode 2)                                                                                                                                                                                                                           | Function<br>(Clock Operating<br>Mode 3)                                                                                                           |

### 4.3 Clock Operating Modes

Table 4.2 shows the relationship between the combinations of the mode control pins (MD\_CLK1 and MD\_CLK0) and the clock operating modes. Table 4.3 shows the usable frequency ranges in the clock operating modes.

**Table 4.2 Clock Operating Modes**

| Mode | Pin Values |         | Clock I/O                   |        | Divider 1 | PLL Circuit On/Off  | CKIO Frequency                   |
|------|------------|---------|-----------------------------|--------|-----------|---------------------|----------------------------------|
|      | MD_CLK1    | MD_CLK0 | Source                      | Output |           |                     |                                  |
| 0    | 0          | 0       | EXTAL or crystal resonator  | CKIO   | 1         | ON<br>(× 8, 12, 16) | (EXTAL or crystal resonator) × 4 |
| 1    | 0          | 1       | EXTAL or crystal resonator  | CKIO   | 1/2       | ON<br>(× 8, 12, 16) | (EXTAL or crystal resonator) × 2 |
| 2    | 1          | 0       | CKIO                        | —      | 1/4       | ON<br>(× 8, 12, 16) | (CKIO)                           |
| 3    | 1          | 1       | USB_X1 or crystal resonator | CKIO   | 1/4       | ON<br>(× 8, 12, 16) | (USB_X1 or crystal resonator)    |

- Mode 0

In mode 0, clock is input from the EXTAL pin or the crystal oscillator. The PLL circuit shapes waveforms and the frequency is multiplied according to the frequency control register setting before the clock is supplied to the LSI. The oscillating frequency for the crystal resonator and EXTAL pin input clock ranges from 10 to 16.67 MHz. The frequency range of CKIO is from 40 to 66.66 MHz. To reduce current consumption, fix the USB\_X1 pin (pull up, pull down, connect to power supply, or connect to ground) and open the USB\_X2 pin when USB is not used.

- Mode 1

In mode 1, clock is input from the EXTAL pin or the crystal oscillator. The PLL circuit shapes waveform and the frequency is multiplied according to the frequency control register setting before the clock is supplied to the LSI. The oscillating frequency for the crystal resonator and EXTAL pin input clock ranges from 20 to 33.33 MHz. The frequency range of CKIO is from 40 to 66.66 MHz. To reduce current consumption, fix the USB\_X1 pin (pull up, pull down, connect to power supply, or connect to ground) and open the USB\_X2 pin when USB is not used.

- Mode 2

In mode 2, the CKIO pin functions as an input pin and draws an external clock signal. The PLL circuit shapes waveform and the frequency is multiplied according to the frequency control register setting before the clock is supplied to the LSI. The frequency range of CKIO is from 40 to 66.66 MHz. To reduce current consumption, fix the EXTAL pin (pull up, pull down, connect to power supply, or connect to ground) and open the XTAL pin when the SH7203 is used in mode 2. When USB is not used, fix the USB\_X1 pin (pull up, pull down, connect to power supply, or connect to ground) and open the USB\_X2 pin.

- Mode 3

In mode 3, clock is input from the USB\_X1 pin or the crystal oscillator. The external clock is input through this pin and waveform is shaped in the PLL circuit. Then the frequency is multiplied according to the frequency control register setting before the clock is supplied to the LSI. The frequency of CKIO is the same as that of the input clock (USB\_X1/crystal resonator) (48 MHz). To reduce current consumption, fix the EXTAL pin (pull up, pull down, connect to power supply, or connect to ground) and open the XTAL pin when the SH7203 is used in mode 3. When the USB crystal resonator is not used, open the USB\_X2 pin.

- Notes:
1. x in the FRQCR register setting depends on the set value in bits 12 and 13.
  2. The ratio of clock frequencies, where the input clock frequency is assumed to be 1.
  3. In mode 0 or 1, the frequency of the EXTAL pin input clock or the crystal resonator  
In mode 2, the frequency of the CKIO pin input clock.  
In mode 3, the frequency of the USB\_X1 pin input clock or the crystal resonator

Caution: Do not use this LSI for frequency settings other than those in table 4.3.

## 4.4 Register Descriptions

The clock pulse generator has the following registers.

**Table 4.4 Register Configuration**

| Register Name              | Abbreviation | R/W | Initial Value | Address    | Access Size |
|----------------------------|--------------|-----|---------------|------------|-------------|
| Frequency control register | FRQCR        | R/W | H'0003        | H'FFFE0010 | 16          |

### 4.4.1 Frequency Control Register (FRQCR)

FRQCR is a 16-bit readable/writable register used to specify whether a clock is output from the CKIO pin during normal operation mode, release of bus mastership, software standby mode and standby mode cancellation. The register also specifies the frequency-multiplier of the PLL circuit and the frequency division ratio for the CPU clock and peripheral clock (P $\phi$ ). FRQCR is accessed by word.

## 4.5 Changing the Frequency

The frequency of the CPU clock ( $I\phi$ ) and peripheral clock ( $P\phi$ ) can be changed either by changing the multiplication rate of PLL circuit or by changing the division rates of divider. All of these are controlled by software through the frequency control register (FRQCR). The methods are described below.

### 4.5.1 Changing the Multiplication Rate

Oscillation settling time must be provided when the multiplication rate of the PLL circuit is changed. The on-chip WDT counts the settling time. The oscillation settling time is the same as when software standby mode is canceled.

1. In the initial state, the multiplication rate of PLL circuit is 8 time.
2. Set a value that will become the specified oscillation settling time in the WDT and stop the WDT. The following must be set:  
WTCSR.TME = 0: WDT stops  
WTCSR.CKS[2:0]: Division ratio of WDT count clock  
WTCNT counter: Initial counter value  
(The WDT count is incremented using the clock after the setting.)
3. Set the desired value in the STC1 and STC0 bits. The division ratio can also be set in the IFC and PFC2 to PFC0 bits.
4. This LSI pauses temporarily and the WDT starts incrementing. A clock is supplied to the WDT only, and the other internal clocks all stop. The clock will continue to be output at the CKIO pin. This state is the same as software standby mode. Whether or not registers are initialized depends on the module. For details, see section 30.3, Register States in Each Operating Mode.
5. Supply of the clock that has been set begins at WDT count overflow, and this LSI begins operating again. The WDT stops after it overflows.

### 4.5.2 Changing the Division Ratio

Counting by the WDT does not proceed if the frequency divisor is changed but the multiplier is not.

1. In the initial state,  $IFC = B'0$  and  $PFC[2:0] = B'011$ .
2. Set the desired value in the IFC and PFC2 to IFC0 bits. The values that can be set are limited by the clock operating mode and the multiplication rate of PLL circuit. Note that if the wrong value is set, this LSI will malfunction.
3. After the register bits (IFC and PFC2 to PFC0) have been set, the clock is supplied of the new division ratio.

Notes:

1. When executing the SLEEP instruction after the frequency has been changed, be sure to read the frequency control register (FRQCR) three times before executing the SLEEP instruction.
2. When the frequency-multiplier of the PLL circuit is changed and while oscillation is settling after exit from software standby mode, an unstable CKIO clock will be output in clock mode 0, 1, or 3. Control bits 14, 13, and 12 in FRQCR to ensure that this unstable CKIO clock does not lead to malfunctions.

## 4.6 Usage of the Clock Pins

For the connection of a crystal resonator or the input of a clock signal, this LSI circuit has the pins listed in table 4.6. With regard to these pins, take care on the following points. Furthermore, Xin pin and Xout pin are used in this section to refer to the pins listed in the table.

**Table 4.6 Clock Pins**

| <b>Xin Pins</b><br><b>(Used for Connection of a Crystal Resonator</b><br><b>and Input of External Clock Signals)</b> | <b>Xout Pins</b><br><b>(Used for Connection of a Crystal Resonator)</b> |
|----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| EXTAL                                                                                                                | XTAL                                                                    |
| USB_X1                                                                                                               | USB_X2                                                                  |
| AUDIO_X1                                                                                                             | AUDIO_X2                                                                |
| RTC_X1                                                                                                               | RTC_X2                                                                  |

### 4.6.1 In the Case of Inputting an External Clock

An example of the connection of an external clock is shown in figure 4.2. In cases where the Xout pin is left open state, take the parasitic capacitance as less than 10 pF.

**Figure 4.2 Example of the Connection of an External Clock**

### 4.6.2 In the Case of Using a Crystal Resonator

An example of the connection of crystal resonator is shown in figure 4.3.

Place the crystal resonator and capacitors (CL1 and CL2) as close to pins Xin and Xout as possible. Furthermore, to avoid inductance so that oscillation is correct, use the points where the capacitors are connected to the crystal resonator in common and do not place wiring patterns close to these components.

Since the design of the user board is closely connected with the effective characteristics of the crystal resonator, refer to the example of connection of the crystal resonator that is introduced in this section and perform thorough evaluation on the user side as well. The rated value of the crystal resonator will vary with the floating capacitances and so on of the crystal resonator and mounted circuit, so proceed with decisions on the basis of full discussions with the maker of the crystal resonator. Ensure that voltages applied to the clock pins do not exceed the maximum rated values.

Although the feedback resistor is included in this LSI, an external feedback resistor may be required in some cases. This depends on the characteristics of the crystal resonator.

Set the parameters (of resistors and capacitors) with thorough evaluation on the user side.

**Figure 4.3 Example of the Connection of a Crystal Resonator**

### 4.6.3 In the Case of Not Using the Clock Pin

In cases where the pins are not in use, fix the level on the  $X_{in}$  pin (pull it up or down, or connect it to the power-supply or ground level), and leave the  $X_{out}$  pin open state.

## 4.7 Oscillation Stabilizing Time

### 4.7.1 Oscillation Stabilizing Time of the On-chip Crystal Oscillator

In the case of using a crystal resonator, please wait longer than the oscillation stabilizing time at the following cases, to keep the oscillation stabilizing time of the on-chip crystal oscillator (In the case of inputting an external clock input, it is not necessary).

- Power on
- Canceling software standby mode or deep standby mode by using the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin
- Changing from halting oscillation to running oscillation by power-on reset or register setting (AUDIO\_X1, RTC\_X1)

### 4.7.2 Oscillation Stabilizing Time of the PLL circuit

In clock mode 0 or 1 the clock input on EXTAL, in clock mode 2 the clock input on CKIO, and in clock mode 3 the clock input on USB\_X1 is supplied to the PLL circuit. So, regardless of whether using a crystal resonator or inputting an external clock from EXTAL (clock mode 0 and 1) or USB\_X1 (clock mode 1 and 3), please wait longer than the oscillation stabilizing time at the following cases, to keep the oscillation stabilizing time of the PLL circuit.

- Power on (in the case of using the crystal resonator)/start inputting external clock (in the case of inputting the external clock)
- Canceling software standby mode or deep standby mode by using the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin
- Changing the multiplication ratio of the PLL circuit by power-on reset from  $\overline{\text{RES}}$  pin

[Remarks]

The oscillation stabilizing time is kept by the counter running in the LSI at the following cases.

- Canceling software standby mode or deep standby mode by using the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin

## 4.8 Notes on Board Design

### 4.8.1 Note on Using a PLL Oscillation Circuit

In the PLLVcc and PLLVss connection pattern for the PLL, signal lines from the board power supply pins must be as short as possible and pattern width must be as wide as possible to reduce inductive interference.

Since the analog power supply pins of the PLL are sensitive to the noise, the system may malfunction due to inductive interference at the other power supply pins. To prevent such malfunction, the analog power supply pin Vcc and digital power supply pin PVcc should not supply the same resources on the board if at all possible.

Ensure that PLLVcc has the same electric potential as Vcc.

**Figure 4.4 Note on Using a PLL Oscillation Circuit**

## 4.9 Usage Note

When this LSI is used in clock mode 0, 1, or 3, the CKIO output will be unstable for one cycle after negation of the  $\overline{\text{RES}}$  signal.

## Section 5 Exception Handling

### 5.1 Overview

#### 5.1.1 Types of Exception Handling and Priority

Exception handling is started by sources, such as resets, address errors, register bank errors, interrupts, and instructions. Table 5.1 shows their priorities. When several exception handling sources occur at once, they are processed according to the priority shown.

**Table 5.1 Types of Exception Handling and Priority Order**

| Type                | Exception Handling                            | Priority                                                                             |
|---------------------|-----------------------------------------------|--------------------------------------------------------------------------------------|
| Reset               | Power-on reset                                |  |
|                     | Manual reset                                  |                                                                                      |
| Address error       | CPU address error                             |                                                                                      |
|                     | DMAC address error                            |                                                                                      |
| Instruction         | Integer division exception (division by zero) |                                                                                      |
|                     | Integer division exception (overflow)         |                                                                                      |
| Register bank error | Bank underflow                                |                                                                                      |
|                     | Bank overflow                                 |                                                                                      |
| Interrupt           | NMI                                           |                                                                                      |
|                     | User break                                    |                                                                                      |
|                     | H-UDI                                         |                                                                                      |
|                     | IRQ                                           |                                                                                      |
|                     | PINT                                          |                                                                                      |
|                     | On-chip peripheral modules                    |                                                                                      |
|                     | Direct memory access controller (DMAC)        |                                                                                      |
|                     | USB2.0 host/function module (USB)             |                                                                                      |
|                     | LCD controller (LCDC)                         |                                                                                      |
|                     | Compare match timer (CMT)                     |                                                                                      |
|                     | Bus state controller (BSC)                    |                                                                                      |
|                     | Watchdog timer (WDT)                          |                                                                                      |
|                     | Multi-function timer pulse unit 2 (MTU2)      |                                                                                      |

| Instruction | Controller area network (RCAN-TL1)                                                                                                                                                                                                                                                                                                                      |                                                          |
|             | Trap instruction (TRAPA instruction)                                                                                                                                                                                                                                                                                                                    |                                                          |
|             | General illegal instructions (undefined code)                                                                                                                                                                                                                                                                                                           |                                                          |
|             | Slot illegal instructions (undefined code placed directly after a delayed branch instruction* <sup>1</sup> (including FPU instructions and FPU-related CPU instructions in FPU module standby state), instructions that rewrite the PC* <sup>2</sup> , 32-bit instructions* <sup>3</sup> , RESBANK instruction, DIVS instruction, and DIVU instruction) |                                                          |

- Notes: 1. Delayed branch instructions: JMP, JSR, BRA, BSR, RTS, RTE, BF/S, BT/S, BSRF, BRAF.
2. Instructions that rewrite the PC: JMP, JSR, BRA, BSR, RTS, RTE, BT, BF, TRAPA, BF/S, BT/S, BSRF, BRAF, JSR/N, RTV/N.
3. 32-bit instructions: BAND.B, BANDNOT.B, BCLR.B, BLD.B, BLDNOT.B, BOR.B, BORNOT.B, BSET.B, BST.B, BXOR.B, MOV.B@disp12, MOV.W@disp12, MOV.L@disp12, MOVI20, MOVI20S, MOVU.B, MOVU.W.

### 5.1.2 Exception Handling Operations

The exception handling sources are detected and start processing according to the timing shown in table 5.2.

**Table 5.2 Timing of Exception Source Detection and Start of Exception Handling**

| Exception           | Source                       | Timing of Source Detection and Start of Handling                                                                                                                                                                                                                                                                                                    |
|---------------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reset               | Power-on reset               | Starts when the $\overline{\text{RES}}$ pin changes from low to high, when the H-UDI reset negate command is set after the H-UDI reset assert command has been set, or when the WDT overflows.                                                                                                                                                      |
|                     | Manual reset                 | Starts when the $\overline{\text{MRES}}$ pin changes from low to high or when the WDT overflows.                                                                                                                                                                                                                                                    |
| Address error       |                              | Detected when instruction is decoded and starts when the previous executing instruction finishes executing.                                                                                                                                                                                                                                         |
| Interrupts          |                              | Detected when instruction is decoded and starts when the previous executing instruction finishes executing.                                                                                                                                                                                                                                         |
| Register bank error | Bank underflow               | Starts upon attempted execution of a RESBANK instruction when saving has not been performed to register banks.                                                                                                                                                                                                                                      |
|                     | Bank overflow                | In the state where saving has been performed to all register bank areas, starts when acceptance of register bank overflow exception has been set by the interrupt controller (the BOVE bit in IBNR of the INTC is 1) and an interrupt that uses a register bank has occurred and been accepted by the CPU.                                          |
| Instructions        | Trap instruction             | Starts from the execution of a TRAPA instruction.                                                                                                                                                                                                                                                                                                   |
|                     | General illegal instructions | Starts from the decoding of undefined code anytime except immediately after a delayed branch instruction (delay slot) (including FPU instructions and FPU-related CPU instructions in FPU module standby state).                                                                                                                                    |
|                     | Slot illegal instructions    | Starts from the decoding of undefined code placed directly after a delayed branch instruction (delay slot) (including FPU instructions and FPU-related CPU instructions in FPU module standby state), of instructions that rewrite the PC, of 32-bit instructions, of the RESBANK instruction, of the DIVS instruction, or of the DIVU instruction. |
|                     | Integer division exception   | Starts when detecting division-by-zero exception or overflow exception caused by division of the negative maximum value (H'80000000) by $-1$ .                                                                                                                                                                                                      |

| Exception    | Source        | Timing of Source Detection and Start of Handling                                                                                                                                                                                                                                                                         |
|--------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Instructions | FPU exception | <p>Starts when detecting invalid operation exception defined by IEEE standard 754, division-by-zero exception, overflow, underflow, or inexact exception.</p> <p>Also starts when qNaN or <math>\pm\infty</math> is input to the source for a floating point operation instruction when the QIS bit in FPSCR is set.</p> |

When exception handling starts, the CPU operates as follows:

### (1) Exception Handling Triggered by Reset

The initial values of the program counter (PC) and stack pointer (SP) are fetched from the exception handling vector table (PC and SP are respectively the H'00000000 and H'00000004 addresses for power-on resets and the H'00000008 and H'0000000C addresses for manual resets). See section 5.1.3, Exception Handling Vector Table, for more information. The vector base register (VBR) is then initialized to H'00000000, the interrupt mask level bits (I3 to I0) of the status register (SR) are initialized to H'F (B'1111), and the BO and CS bits are initialized. The BN bit in IBNR of the interrupt controller (INTC) is also initialized to 0. The floating point status/control register (FPSCR) is initialized to H'00040001 by a power-on reset. The program begins running from the PC address fetched from the exception handling vector table.

### (2) Exception Handling Triggered by Address Errors, Register Bank Errors, Interrupts, and Instructions

SR and PC are saved to the stack indicated by R15. In the case of interrupt exception handling other than NMI or user breaks with usage of the register banks enabled, general registers R0 to R14, control register GBR, system registers MACH, MACL, and PR, and the vector table address offset of the interrupt exception handling to be executed are saved to the register banks. In the case of exception handling due to an address error, register bank error, NMI interrupt, user break interrupt, or instruction, saving to a register bank is not performed. When saving is performed to all register banks, automatic saving to the stack is performed instead of register bank saving. In this case, an interrupt controller setting must have been made so that register bank overflow exceptions are not accepted (the BOVE bit in IBNR of the INTC is 0). If a setting to accept register bank overflow exceptions has been made (the BOVE bit in IBNR of the INTC is 1), register bank overflow exception will be generated. In the case of interrupt exception handling, the interrupt priority level is written to the I3 to I0 bits in SR. In the case of exception handling due to an address error or instruction, the I3 to I0 bits are not affected. The exception service routine start address is then fetched from the exception handling vector table and the program begins running from that address.

### 5.1.3 Exception Handling Vector Table

Before exception handling begins running, the exception handling vector table must be set in memory. The exception handling vector table stores the start addresses of exception service routines. (The reset exception handling table holds the initial values of PC and SP.)

All exception sources are given different vector numbers and vector table address offsets, from which the vector table addresses are calculated. During exception handling, the start addresses of the exception service routines are fetched from the exception handling vector table, which is indicated by this vector table address.

Table 5.3 shows the vector numbers and vector table address offsets. Table 5.4 shows how vector table addresses are calculated.

**Table 5.3 Exception Handling Vector Table**

| Exception Sources           |            | Vector Numbers | Vector Table Address Offset |
|-----------------------------|------------|----------------|-----------------------------|
| Power-on reset              | PC         | 0              | H'00000000 to H'00000003    |
|                             | SP         | 1              | H'00000004 to H'00000007    |
| Manual reset                | PC         | 2              | H'00000008 to H'0000000B    |
|                             | SP         | 3              | H'0000000C to H'0000000F    |
| General illegal instruction |            | 4              | H'00000010 to H'00000013    |
| (Reserved by system)        |            | 5              | H'00000014 to H'00000017    |
| Slot illegal instruction    |            | 6              | H'00000018 to H'0000001B    |
| (Reserved by system)        |            | 7              | H'0000001C to H'0000001F    |
|                             |            | 8              | H'00000020 to H'00000023    |
| CPU address error           |            | 9              | H'00000024 to H'00000027    |
| DMAC address error          |            | 10             | H'00000028 to H'0000002B    |
| Interrupts                  | NMI        | 11             | H'0000002C to H'0000002F    |
|                             | User break | 12             | H'00000030 to H'00000033    |
| FPU exception               |            | 13             | H'00000034 to H'00000037    |
| H-UDI                       |            | 14             | H'00000038 to H'0000003B    |
| Bank overflow               |            | 15             | H'0000003C to H'0000003F    |
| Bank underflow              |            | 16             | H'00000040 to H'00000043    |

| Exception Sources                                                      | Vector Numbers | Vector Table Address Offset |
|------------------------------------------------------------------------|----------------|-----------------------------|
| Integer division exception (division by zero)                          | 17             | H'00000044 to H'00000047    |
| Integer division exception (overflow)                                  | 18             | H'00000048 to H'0000004B    |
| (Reserved by system)                                                   | 19             | H'0000004C to H'0000004F    |
|                                                                        | :              | :                           |
|                                                                        | 31             | H'0000007C to H'0000007F    |
| Trap instruction (user vector)                                         | 32             | H'00000080 to H'00000083    |
|                                                                        | :              | :                           |
|                                                                        | 63             | H'000000FC to H'000000FF    |
| External interrupts (IRQ, PINT), on-chip peripheral module interrupts* | 64             | H'00000100 to H'00000103    |
|                                                                        | :              | :                           |
|                                                                        | 511            | H'000007FC to H'000007FF    |

Note: \* The vector numbers and vector table address offsets for each external interrupt and on-chip peripheral module interrupt are given in table 6.4.

**Table 5.4 Calculating Exception Handling Vector Table Addresses**

| Exception Source                                               | Vector Table Address Calculation                                                          |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| Resets                                                         | Vector table address = (vector table address offset)<br>= (vector number) × 4             |
| Address errors, register bank errors, interrupts, instructions | Vector table address = VBR + (vector table address offset)<br>= VBR + (vector number) × 4 |

Notes: 1. Vector table address offset: See table 5.3.  
2. Vector number: See table 5.3.

## 5.2 Resets

### 5.2.1 Input/Output Pins

Table 5.5 shows the reset-related pin configuration.

**Table 5.5 Pin Configuration**

| Pin Name       | Symbol                   | I/O   | Function                                                                      |
|----------------|--------------------------|-------|-------------------------------------------------------------------------------|
| Power-on reset | $\overline{\text{RES}}$  | Input | When this pin is driven low, this LSI shifts to the power-on reset processing |
| Manual reset   | $\overline{\text{MRES}}$ | Input | When this pin is driven low, this LSI shifts to the manual reset processing.  |

### 5.2.2 Types of Reset

A reset is the highest-priority exception handling source. There are two kinds of reset, power-on and manual. As shown in table 5.6, the CPU state is initialized in both a power-on reset and a manual reset. The FPU state is initialized by a power-on reset, but not by a manual reset. On-chip peripheral module registers except a few registers are also initialized by a power-on reset, but not by a manual reset.

**Table 5.6 Reset States**

| Type           | Conditions for Transition to Reset State |                                              |                          |                | Internal States |                |                                                |                            |
|----------------|------------------------------------------|----------------------------------------------|--------------------------|----------------|-----------------|----------------|------------------------------------------------|----------------------------|
|                | $\overline{\text{RES}}$                  | H-UDI Command                                | $\overline{\text{MRES}}$ | WDT Overflow   | CPU             | Other Modules  | On-Chip High-Speed RAM                         | On-Chip Data Retention RAM |
| Power-on reset | Low                                      | —                                            | —                        | —              | Initialized     | Initialized    | Initialized or retained contents* <sup>2</sup> | Initialized                |
|                | High                                     | H-UDI reset assert command is set            | —                        | —              | Initialized     | Initialized    | Initialized or retained contents* <sup>2</sup> | Initialized                |
|                | High                                     | Command other than H-UDI reset assert is set | —                        | Power-on reset | Initialized     | * <sup>1</sup> | Initialized or retained contents* <sup>2</sup> | Initialized                |
| Manual reset   | High                                     | Command other than H-UDI reset assert is set | Low                      | —              | Initialized     | * <sup>1</sup> | Retained contents                              | Retained contents          |
|                | High                                     | Command other than H-UDI reset assert is set | High                     | Manual reset   | Initialized     | * <sup>1</sup> | Retained contents                              | Retained contents          |

Notes: 1. See section 30.3, Register States in Each Operating Mode.

2. Data are retained when the setting of either the RAME or RAMWE bit is disabled.

### 5.2.3 Power-On Reset

#### (1) Power-On Reset by Means of $\overline{\text{RES}}$ Pin

When the  $\overline{\text{RES}}$  pin is driven low, this LSI enters the power-on reset state. To reliably reset this LSI, the  $\overline{\text{RES}}$  pin should be kept at the low level for the duration of the oscillation settling time at power-on or when in software standby mode (when the clock is halted), or at least 20- $t_{\text{cyc}}$  (unfixed) when the clock is running. In the power-on reset state, the internal state of the CPU and all the on-chip peripheral module registers are initialized. See appendix A, Pin States, for the status of individual pins during the power-on reset state.

In the power-on reset state, power-on reset exception handling starts when the  $\overline{\text{RES}}$  pin is first driven low for a fixed period and then returned to high. The CPU operates as follows:

1. The initial value (execution start address) of the program counter (PC) is fetched from the exception handling vector table.
2. The initial value of the stack pointer (SP) is fetched from the exception handling vector table.
3. The vector base register (VBR) is cleared to H'00000000, the interrupt mask level bits (I3 to I0) of the status register (SR) are initialized to H'F (B'1111), and the BO and CS bits are initialized. The BN bit in IBNR of the INTC is also initialized to 0. FPSCR is initialized to H'00040001
4. The values fetched from the exception handling vector table are set in the PC and SP, and the program begins executing.

Be certain to always perform power-on reset processing when turning the system power on.

#### (2) Power-On Reset by Means of H-UDI Reset Assert Command

When the H-UDI reset assert command is set, this LSI enters the power-on reset state. Power-on reset by means of an H-UDI reset assert command is equivalent to power-on reset by means of the  $\overline{\text{RES}}$  pin. Setting the H-UDI reset negate command cancels the power-on reset state. The time required between an H-UDI reset assert command and H-UDI reset negate command is the same as the time to keep the  $\overline{\text{RES}}$  pin low to initiate a power-on reset. In the power-on reset state generated by an H-UDI reset assert command, setting the H-UDI reset negate command starts power-on reset exception handling. The CPU operates in the same way as when a power-on reset was caused by the  $\overline{\text{RES}}$  pin.

### (3) Power-On Reset Initiated by WDT

When a setting is made for a power-on reset to be generated in the WDT's watchdog timer mode, and WTCNT of the WDT overflows, this LSI enters the power-on reset state.

In this case, WRCSR of the WDT and FRQCR of the CPG are not initialized by the reset signal generated by the WDT.

If a reset caused by the  $\overline{\text{RES}}$  pin or the H-UDI reset assert command occurs simultaneously with a reset caused by WDT overflow, the reset caused by the  $\overline{\text{RES}}$  pin or the H-UDI reset assert command has priority, and the WOVF bit in WRCSR is cleared to 0. When power-on reset exception processing is started by the WDT, the CPU operates in the same way as when a power-on reset was caused by the  $\overline{\text{RES}}$  pin.

## 5.2.4 Manual Reset

### (1) Manual Reset by Means of $\overline{\text{MRES}}$ Pin

When the  $\overline{\text{MRES}}$  pin is driven low, this LSI enters the manual reset state. To reset this LSI without fail, the  $\overline{\text{MRES}}$  pin should be kept at the low level for at least 20- $t_{\text{cyc}}$ . In the manual reset state, the CPU's internal state is initialized, but all the on-chip peripheral module registers are not initialized. In the manual reset state, manual reset exception handling starts when the  $\overline{\text{MRES}}$  pin is first driven low for a fixed period and then returned to high. The CPU operates as follows:

1. The initial value (execution start address) of the program counter (PC) is fetched from the exception handling vector table.
2. The initial value of the stack pointer (SP) is fetched from the exception handling vector table.
3. The vector base register (VBR) is cleared to H'00000000, the interrupt mask level bits (I3 to I0) of the status register (SR) are initialized to H'F (B'1111), and the BO and CS bits are initialized. The BN bit in IBNR of the INTC is also initialized to 0.
4. The values fetched from the exception handling vector table are set in the PC and SP, and the program begins executing.

### (2) Manual Reset Initiated by WDT

When a setting is made for a manual reset to be generated in the WDT's watchdog timer mode, and WTCNT of the WDT overflows, this LSI enters the manual reset state.

When manual reset exception processing is started by the WDT, the CPU operates in the same way as when a manual reset was caused by the  $\overline{\text{MRES}}$  pin.

### (3) Note in Manual Reset

When a manual reset is generated, the bus cycle is retained, but if a manual reset occurs while the bus is released or during DMAC burst transfer, manual reset exception handling will be deferred until the CPU acquires the bus. The CPU and the BN bit in IBNR of the INTC are initialized by a manual reset. The FPU and other modules are not initialized.

## 5.3 Address Errors

### 5.3.1 Address Error Sources

Address errors occur when instructions are fetched or data read or written, as shown in table 5.7.

**Table 5.7 Bus Cycles and Address Errors**

| <b>Bus Cycle</b>  |                   |                                                                                                                        |                       |
|-------------------|-------------------|------------------------------------------------------------------------------------------------------------------------|-----------------------|
| <b>Type</b>       | <b>Bus Master</b> | <b>Bus Cycle Description</b>                                                                                           | <b>Address Errors</b> |
| Instruction fetch | CPU               | Instruction fetched from even address                                                                                  | None (normal)         |
|                   |                   | Instruction fetched from odd address                                                                                   | Address error occurs  |
|                   |                   | Instruction fetched from other than on-chip peripheral module space* or H'F0000000 to H'F5FFFFFF in on-chip RAM space* | None (normal)         |
|                   |                   | Instruction fetched from on-chip peripheral module space* or H'F0000000 to H'F5FFFFFF in on-chip RAM space*            | Address error occurs  |
| Data read/write   | CPU or DMAC       | Word data accessed from even address                                                                                   | None (normal)         |
|                   |                   | Word data accessed from odd address                                                                                    | Address error occurs  |
|                   |                   | Longword data accessed from a longword boundary                                                                        | None (normal)         |
|                   |                   | Longword data accessed from other than a long-word boundary                                                            | Address error occurs  |
|                   |                   | Double longword data accessed from a double longword boundary                                                          | None (normal)         |
|                   |                   | Double longword data accessed from other than a double longword boundary                                               | Address error occurs  |
|                   |                   | Byte or word data accessed in on-chip peripheral module space*                                                         | None (normal)         |
|                   |                   | Longword data accessed in 16-bit on-chip peripheral module space*                                                      | None (normal)         |
|                   |                   | Longword data accessed in 8-bit on-chip peripheral module space*                                                       | None (normal)         |

Note: \* See section 9, Bus State Controller (BSC), for details of the on-chip peripheral module space and on-chip RAM space.

### 5.3.2 Address Error Exception Handling

When an address error occurs, the bus cycle in which the address error occurred ends.\* When the executing instruction then finishes, address error exception handling starts. The CPU operates as follows:

1. The exception service routine start address which corresponds to the address error that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the last executed instruction.
4. After jumping to the exception service routine start address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

Note: \* In the case of address error related to data read/write. In the case of address error related to instruction fetch, if the bus cycle in which the address error occurred doesn't end until the entire three above-mentioned operations end, the CPU will start address error exception handling again until the bus cycle in which the address error occurred ends.

## 5.4 Register Bank Errors

### 5.4.1 Register Bank Error Sources

#### (1) Bank Overflow

In the state where saving has already been performed to all register bank areas, bank overflow occurs when acceptance of register bank overflow exception has been set by the interrupt controller (the BOVE bit in IBNR of the INTC is set to 1) and an interrupt that uses a register bank has occurred and been accepted by the CPU.

#### (2) Bank Underflow

Bank underflow occurs when an attempt is made to execute a RESBANK instruction while saving has not been performed to register banks.

### 5.4.2 Register Bank Error Exception Handling

When a register bank error occurs, register bank error exception handling starts. The CPU operates as follows:

1. The exception service routine start address which corresponds to the register bank error that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the last executed instruction for a bank overflow, and the start address of the executed RESBANK instruction for a bank underflow.

To prevent multiple interrupts from occurring at a bank overflow, the interrupt priority level that caused the bank overflow is written to the interrupt mask level bits (I3 to I0) of the status register (SR).

4. After jumping to the exception service routine start address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

## 5.5 Interrupts

### 5.5.1 Interrupt Sources

Table 5.8 shows the sources that start interrupt exception handling. These are divided into NMI, user breaks, H-UDI, IRQ, PINT, and on-chip peripheral modules.

**Table 5.8 Interrupt Sources**

| Type                      | Request Source                                   | Number of Sources |
|---------------------------|--------------------------------------------------|-------------------|
| NMI                       | NMI pin (external input)                         | 1                 |
| User break                | User break controller (UBC)                      | 1                 |
| H-UDI                     | User debugging interface (H-UDI)                 | 1                 |
| IRQ                       | IRQ0 to IRQ7 pins (external input)               | 8                 |
| PINT                      | PINT0 to PINT7 pins (external input)             | 8                 |
| On-chip peripheral module | Direct memory access controller (DMAC)           | 16                |
|                           | USB2.0 host/function module (USB)                | 1                 |
|                           | LCD controller (LCDC)                            | 1                 |
|                           | Compare match timer (CMT)                        | 2                 |
|                           | Bus state controller (BSC)                       | 1                 |
|                           | Watchdog timer (WDT)                             | 1                 |
|                           | Multi-function timer pulse unit 2 (MTU2)         | 25                |
|                           | A/D converter (ADC)                              | 1                 |
|                           | I <sup>2</sup> C bus interface 3 (IIC3)          | 20                |
|                           | Serial communications interface with FIFO (SCIF) | 16                |
|                           | Synchronous serial communications unit (SSU)     | 6                 |
|                           | Serial sound interface (SSI)                     | 4                 |
|                           | AND/NAND flash memory controller (FLCTL)         | 4                 |
|                           | Realtime clock (RTC)                             | 3                 |
|                           | Controller area network (RCAN-TL1)               | 10                |

Each interrupt source is allocated a different vector number and vector table offset. See table 6.4, for more information on vector numbers and vector table address offsets.

### 5.5.2 Interrupt Priority Level

The interrupt priority order is predetermined. When multiple interrupts occur simultaneously (overlap), the interrupt controller (INTC) determines their relative priorities and starts processing according to the results.

The priority order of interrupts is expressed as priority levels 0 to 16, with priority 0 the lowest and priority 16 the highest. The NMI interrupt has priority 16 and cannot be masked, so it is always accepted. The user break interrupt and H-UDI interrupt priority level is 15. Priority levels of IRQ interrupts, PINT interrupts, and on-chip peripheral module interrupts can be set freely using the interrupt priority registers 01, 02, and 05 to 17 (IPR01, IPR02, and IPR05 to IPR17) of the INTC as shown in table 5.9. The priority levels that can be set are 0 to 15. Level 16 cannot be set. See section 6.3.1, Interrupt Priority Registers 01, 02, 05 to 17 (IPR01, IPR02, IPR05 to IPR17), for details of IPR01, IPR02, and IPR05 to IPR17.

**Table 5.9 Interrupt Priority Order**

| Type                      | Priority Level | Comment                                                                                        |
|---------------------------|----------------|------------------------------------------------------------------------------------------------|
| NMI                       | 16             | Fixed priority level. Cannot be masked.                                                        |
| User break                | 15             | Fixed priority level.                                                                          |
| H-UDI                     | 15             | Fixed priority level.                                                                          |
| IRQ                       | 0 to 15        | Set with interrupt priority registers 01, 02, and 05 to 17 (IPR01, IPR02, and IPR05 to IPR17). |
| PINT                      |                |                                                                                                |
| On-chip peripheral module |                |                                                                                                |

### 5.5.3 Interrupt Exception Handling

When an interrupt occurs, its priority level is ascertained by the interrupt controller (INTC). NMI is always accepted, but other interrupts are only accepted if they have a priority level higher than the priority level set in the interrupt mask level bits (I3 to I0) of the status register (SR).

When an interrupt is accepted, interrupt exception handling begins. In interrupt exception handling, the CPU fetches the exception service routine start address which corresponds to the accepted interrupt from the exception handling vector table, and saves SR and the program counter (PC) to the stack. In the case of interrupt exception handling other than NMI or user breaks with usage of the register banks enabled, general registers R0 to R14, control register GBR, system registers MACH, MACL, and PR, and the vector table address offset of the interrupt exception handling to be executed are saved in the register banks. In the case of exception handling due to an address error, NMI interrupt, user break interrupt, or instruction, saving is not performed to the register banks. If saving has been performed to all register banks (0 to 14), automatic saving to the stack is performed instead of register bank saving. In this case, an interrupt controller setting must have been made so that register bank overflow exceptions are not accepted (the BOVE bit in IBNR of the INTC is 0). If a setting to accept register bank overflow exceptions has been made (the BOVE bit in IBNR of the INTC is 1), register bank overflow exception occurs. Next, the priority level value of the accepted interrupt is written to the I3 to I0 bits in SR. For NMI, however, the priority level is 16, but the value set in the I3 to I0 bits is H'F (level 15). Then, after jumping to the start address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch. See section 6.6, Operation, for further details of interrupt exception handling.

## 5.6 Exceptions Triggered by Instructions

### 5.6.1 Types of Exceptions Triggered by Instructions

Exception handling can be triggered by trap instructions, slot illegal instructions, general illegal instructions, integer division exceptions, and FPU exceptions, as shown in table 5.10.

**Table 5.10 Types of Exceptions Triggered by Instructions**

| Type                         | Source Instruction                                                                                                                                                                                                                                                                              | Comment                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Trap instruction             | TRAPA                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                 |
| Slot illegal instructions    | Undefined code placed immediately after a delayed branch instruction (delay slot) (including FPU instructions and FPU-related CPU instructions in FPU module standby state), instructions that rewrite the PC, 32-bit instructions, RESBANK instruction, DIVS instruction, and DIVU instruction | Delayed branch instructions: JMP, JSR, BRA, BSR, RTS, RTE, BF/S, BT/S, BSRF, BRAF<br>Instructions that rewrite the PC: JMP, JSR, BRA, BSR, RTS, RTE, BT, BF, TRAPA, BF/S, BT/S, BSRF, BRAF, JSR/N, RTV/N<br>32-bit instructions: BAND.B, BANDNOT.B, BCLR.B, BLD.B, BLDNOT.B, BOR.B, BORNOT.B, BSET.B, BST.B, BXOR.B, MOV.B@disp12, MOV.W@disp12, MOV.L@disp12, MOVI20, MOVI20S, MOVU.B, MOVU.W. |
| General illegal instructions | Undefined code anywhere besides in a delay slot (including FPU instructions and FPU-related CPU instructions in FPU module standby statute)                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                 |
| Integer division exceptions  | Division by zero                                                                                                                                                                                                                                                                                | DIVU, DIVS                                                                                                                                                                                                                                                                                                                                                                                      |
|                              | Negative maximum value $\div (-1)$                                                                                                                                                                                                                                                              | DIVS                                                                                                                                                                                                                                                                                                                                                                                            |
| FPU exceptions               | Starts when detecting invalid operation exception defined by IEEE754, division-by-zero exception, overflow, underflow, or inexact exception.                                                                                                                                                    | FADD, FSUB, FMUL, FDIV, FMAC, FCMP/EQ, FCMP/GT, FLOAT, FTRC, FCNVDS, FCNVSD, FSQRT                                                                                                                                                                                                                                                                                                              |

### 5.6.2 Trap Instructions

When a TRAPA instruction is executed, trap instruction exception handling starts. The CPU operates as follows:

1. The exception service routine start address which corresponds to the vector number specified in the TRAPA instruction is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the TRAPA instruction.
4. After jumping to the exception service routine start address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

### 5.6.3 Slot Illegal Instructions

An instruction placed immediately after a delayed branch instruction is said to be placed in a delay slot. When the instruction placed in the delay slot is undefined code (including FPU instructions and FPU-related CPU instructions in FPU module standby state), an instruction that rewrites the PC, a 32-bit instruction, an RESBANK instruction, a DIVS instruction, or a DIVU instruction, slot illegal exception handling starts when such kind of instruction is decoded. When the FPU has entered a module standby state, the floating point operation instruction and FPU-related CPU instructions are handled as undefined codes. If these instructions are placed in a delay slot and then decoded, a slot illegal instruction exception handling starts.

The CPU operates as follows:

1. The exception service routine start address is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the jump address of the delayed branch instruction immediately before the undefined code, the instruction that rewrites the PC, the 32-bit instruction, the RESBANK instruction, the DIVS instruction, or the DIVU instruction.
4. After jumping to the exception service routine start address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

### 5.6.4 General Illegal Instructions

When an undefined code, including FPU instructions and FPU-related CPU instructions in FPU module standby state, placed anywhere other than immediately after a delayed branch instruction, i.e., in a delay slot, is decoded, general illegal instruction exception handling starts. When the FPU has entered a module standby state, the floating point instruction and FPU-related CPU instructions are handled as undefined codes. If these instructions are placed anywhere other than immediately after a delayed branch instruction (i.e., in a delay slot) and then decoded, general illegal instruction exception handling starts.

In general illegal instruction exception handling, the CPU handles general illegal instructions in the same way as slot illegal instructions. Unlike processing of slot illegal instructions, however, the program counter value stored is the start address of the undefined code.

### 5.6.5 Integer Division Exceptions

When an integer division instruction performs division by zero or the result of integer division overflows, integer division instruction exception handling starts. The instructions that may become the source of division-by-zero exception are DIVU and DIVS. The only source instruction of overflow exception is DIVS, and overflow exception occurs only when the negative maximum value is divided by  $-1$ . The CPU operates as follows:

1. The exception service routine start address which corresponds to the integer division exception that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the integer division instruction at which the exception occurred.
4. After jumping to the exception service routine start address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

### 5.6.6 FPU Exceptions

FPU exception handling takes place when the V, Z, O, U, or I bit in the FPU enable field (Enable) of the floating point status/control register (FPSCR) is set to 1. This indicates the occurrence of an invalid operation exception defined by the IEEE 754 standard, a division-by-zero exception, an overflow (in the case of an instruction for which this is possible), an underflow (in the case of an instruction for which this is possible), or an inexact exception (in the case of an instruction for which this is possible).

The instructions that may trigger FPU exception handling are FADD, FSUB, FMUL, FDIV, FMAC, FCMP/EQ, FCMP/GT, FLOAT, FTRC, FCNVDS, FCNVSD, and FSQRT.

FPU exception handling occurs only when the corresponding FPU exception enable bit (Enable) is set to 1. When an exception source triggered by a floating-point operation is detected, FPU operation is halted and the occurrence of FPU exception handling is reported to the CPU. When exception handling starts, the CPU operates as follows:

1. The start address of the exception service routine which corresponds to the FPU exception handling that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved on the stack.
3. The program counter (PC) is saved on the stack. The PC value saved is the start address of the instruction to be executed after the last executed instruction.
4. After jumping to the address fetched from the exception handling vector table, program execution starts. This jump is not a delayed branch.

The FPU exception flag field (Flag) of FPSCR is always updated regardless of whether or not FPU exception handling has been accepted, and remains set until explicitly cleared by the user through an instruction. The FPU exception source field (Cause) of FPSCR changes each time a floating-point instruction is executed.

When the V bit in the FPU exception enable field (Enable) of FPSCR and the QIS bit in FPSCR are both set to 1, FPU exception handling occurs when qNaN or  $\pm\infty$  is input to a floating-point operation instruction source.

## 5.7 When Exception Sources Are Not Accepted

When an address error, FPU exception, register bank error (overflow), or interrupt is generated immediately after a delayed branch instruction, it is sometimes not accepted immediately but stored instead, as shown in table 5.11. When this happens, it will be accepted when an instruction that can accept the exception is decoded.

**Table 5.11 Exception Source Generation Immediately after Delayed Branch Instruction**

| Point of Occurrence                             | Exception Source |               |                                |              |
|-------------------------------------------------|------------------|---------------|--------------------------------|--------------|
|                                                 | Address Error    | FPU Exception | Register Bank Error (Overflow) | Interrupt    |
| Immediately after a delayed branch instruction* | Not accepted     | Not accepted  | Not accepted                   | Not accepted |

Note: \* Delayed branch instructions: JMP, JSR, BRA, BSR, RTS, RTE, BF/S, BT/S, BSRF, BRAF

## 5.8 Stack Status after Exception Handling Ends

The status of the stack after exception handling ends is as shown in table 5.12.

**Table 5.12 Stack Status After Exception Handling Ends**

| Exception Type                  | Stack Status |                                                        |         |
|---------------------------------|--------------|--------------------------------------------------------|---------|
| Address error                   | SP →         | Address of instruction after executed instruction      | 32 bits |
|                                 |              | SR                                                     | 32 bits |
| Interrupt                       | SP →         | Address of instruction after executed instruction      | 32 bits |
|                                 |              | SR                                                     | 32 bits |
| Register bank error (overflow)  | SP →         | Address of instruction after executed instruction      | 32 bits |
|                                 |              | SR                                                     | 32 bits |
| Register bank error (underflow) | SP →         | Start address of relevant RESBANK instruction          | 32 bits |
|                                 |              | SR                                                     | 32 bits |
| Trap instruction                | SP →         | Address of instruction after TRAPA instruction         | 32 bits |
|                                 |              | SR                                                     | 32 bits |
| Slot illegal instruction        | SP →         | Jump destination address of delayed branch instruction | 32 bits |
|                                 |              | SR                                                     | 32 bits |

| Exception Type              | Stack Status                                                                                                                                                       |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| General illegal instruction | <div><div>SP →</div><div><div>Start address of general illegal instruction</div><div>32 bits</div></div><div><div>SR</div><div>32 bits</div></div></div>           |
| Integer division exception  | <div><div>SP →</div><div><div>Start address of relevant integer division instruction</div><div>32 bits</div></div><div><div>SR</div><div>32 bits</div></div></div> |
| FPU exception               | <div><div>SP →</div><div><div>Address of instruction after executed instruction</div><div>32 bits</div></div><div><div>SR</div><div>32 bits</div></div></div>      |

## 5.9 Usage Notes

### 5.9.1 Value of Stack Pointer (SP)

The value of the stack pointer must always be a multiple of four. If it is not, an address error will occur when the stack is accessed during exception handling.

### 5.9.2 Value of Vector Base Register (VBR)

The value of the vector base register must always be a multiple of four. If it is not, an address error will occur when the stack is accessed during exception handling.

### 5.9.3 Address Errors Caused by Stacking of Address Error Exception Handling

When the stack pointer is not a multiple of four, an address error will occur during stacking of the exception handling (interrupts, etc.) and address error exception handling will start up as soon as the first exception handling is ended. Address errors will then also occur in the stacking for this address error exception handling. To ensure that address error exception handling does not go into an endless loop, no address errors are accepted at that point. This allows program control to be shifted to the address error exception service routine and enables error processing.

When an address error occurs during exception handling stacking, the stacking bus cycle (write) is executed. During stacking of the status register (SR) and program counter (PC), the SP is decremented by 4 for both, so the value of SP will not be a multiple of four after the stacking either. The address value output during stacking is the SP value, so the address where the error occurred is itself output. This means the write data stacked will be undefined.

### 5.9.4 Interrupt Control via Modification of Interrupt Mask Bits

When enabling interrupts by changing the Interrupt Mask bits (I3-I0) of the Status Register (SR) using the LDC or LDC.L instructions, interrupts might not be accepted during the execution of the 5 instructions immediately after the LDC/LDC.L instruction.

Therefore, when enabling/disabling interrupts by changing the Interrupt Mask bits (I3-I0) of the Status Register (SR) using LDC/LDC.L instructions, please place at least 5 instructions between the interrupt-enable instruction and the interrupt-disable instruction.

### 5.9.5 Note before Exception Handling Begins Running

Before exception handling begins running, the exception handling vector table must be stored in a memory, and the CPU must be able to access the memory. So, if the exception handling is generated

- Ex. 1: when the exception handling vector table is stored in an external address space, but the settings of bus state controller and general I/O ports to access the external address space have been not completed yet, or
  - Ex. 2: when the exception handling vector table is stored in the on-chip RAM, but the vector base register (VBR) has been not changed to the on-chip RAM address yet,
- the CPU fetches an unintended value as the execution start address, and starts executing programs from unintended address.

## Section 6 Interrupt Controller (INTC)

The interrupt controller (INTC) ascertains the priority of interrupt sources and controls interrupt requests to the CPU. The INTC registers set the order of priority of each interrupt, allowing the user to process interrupt requests according to the user-set priority.

### 6.1 Features

- 16 levels of interrupt priority can be set

By setting the fifteen interrupt priority registers, the priorities of IRQ interrupts, PINT interrupts, and on-chip peripheral module interrupts can be selected from 16 levels for request sources.

- NMI noise canceler function

An NMI input-level bit indicates the NMI pin state. By reading this bit in the interrupt exception service routine, the pin state can be checked, enabling it to be used as the noise canceler function.

- Occurrence of interrupt can be reported externally ( $\overline{\text{IRQOUT}}$  pin)

For example, when this LSI has released the bus mastership, this LSI can inform the external bus master of occurrence of an on-chip peripheral module interrupt and request for the bus mastership.

- Register banks

This LSI has register banks that enable register saving and restoration required in the interrupt processing to be performed at high speed.

Figure 6.1 shows a block diagram of the INTC.

**Figure 6.1 Block Diagram of INTC**

## 6.2 Input/Output Pins

Table 6.1 shows the pin configuration of the INTC.

**Table 6.1 Pin Configuration**

| Pin Name                        | Symbol                     | I/O    | Function                                                  |
|---------------------------------|----------------------------|--------|-----------------------------------------------------------|
| Nonmaskable interrupt input pin | NMI                        | Input  | Input of nonmaskable interrupt request signal             |
| Interrupt request input pins    | IRQ7 to IRQ0               | Input  | Input of maskable interrupt request signals               |
|                                 | PINT7 to PINT0             | Input  |                                                           |
| Interrupt request output pin    | $\overline{\text{IRQOUT}}$ | Output | Output of signal to report occurrence of interrupt source |

## 6.3 Register Descriptions

The INTC has the following registers. These registers are used to set the interrupt priorities and control detection of the external interrupt input signal.

**Table 6.2 Register Configuration**

| Register Name                   | Abbreviation | R/W                 | Initial Value  | Address    | Access Size |
|---------------------------------|--------------|---------------------|----------------|------------|-------------|
| Interrupt control register 0    | ICR0         | R/W                 | * <sup>1</sup> | H'FFFE0800 | 16, 32      |
| Interrupt control register 1    | ICR1         | R/W                 | H'0000         | H'FFFE0802 | 16, 32      |
| Interrupt control register 2    | ICR2         | R/W                 | H'0000         | H'FFFE0804 | 16, 32      |
| IRQ interrupt request register  | IRQRR        | R/(W)* <sup>2</sup> | H'0000         | H'FFFE0806 | 16, 32      |
| PINT interrupt enable register  | PINTER       | R/W                 | H'0000         | H'FFFE0808 | 16, 32      |
| PINT interrupt request register | PIRR         | R                   | H'0000         | H'FFFE080A | 16, 32      |
| Bank control register           | IBCR         | R/W                 | H'0000         | H'FFFE080C | 16, 32      |
| Bank number register            | IBNR         | R/W                 | H'0000         | H'FFFE080E | 16, 32      |
| Interrupt priority register 01  | IPR01        | R/W                 | H'0000         | H'FFFE0818 | 16, 32      |
| Interrupt priority register 02  | IPR02        | R/W                 | H'0000         | H'FFFE081A | 16, 32      |
| Interrupt priority register 05  | IPR05        | R/W                 | H'0000         | H'FFFE0820 | 16, 32      |
| Interrupt priority register 06  | IPR06        | R/W                 | H'0000         | H'FFFE0C00 | 16, 32      |

| Interrupt priority register 12  | IPR12        | R/W                 | H'0000         | H'FFFE0C0C | 16, 32      |
| Interrupt priority register 13  | IPR13        | R/W                 | H'0000         | H'FFFE0C0E | 16, 32      |
| Interrupt priority register 14  | IPR14        | R/W                 | H'0000         | H'FFFE0C10 | 16, 32      |
| Interrupt priority register 15  | IPR15        | R/W                 | H'0000         | H'FFFE0C12 | 16, 32      |
| Interrupt priority register 16  | IPR16        | R/W                 | H'0000         | H'FFFE0C14 | 16, 32      |
| Interrupt priority register 17  | IPR17        | R/W                 | H'0000         | H'FFFE0C16 | 16, 32      |

Notes: 1. When the NMI pin is high, becomes H'8000; when low, becomes H'0000.

2. Only 0 can be written after reading 1, to clear the flag.

### 6.3.1 Interrupt Priority Registers 01, 02, 05 to 17 (IPR01, IPR02, IPR05 to IPR17)

IPR01, IPR02, and IPR05 to IPR17 are 16-bit readable/writable registers in which priority levels from 0 to 15 are set for IRQ interrupts, PINT interrupts, and on-chip peripheral module interrupts. Table 6.3 shows the correspondence between the interrupt request sources and the bits in IPR01, IPR02, and IPR05 to IPR17.

| Interrupt priority register 07 | DMAC4                    | DMAC5                  | DMAC6                    | DMAC7                            |
| Interrupt priority register 08 | USB                      | LCDC                   | CMT0                     | CMT1                             |
| Interrupt priority register 09 | BSC                      | WDT                    | MTU0<br>(TGI0A to TGI0D) | MTU0<br>(TCI0V, TGI0E,<br>TGI0F) |
| Interrupt priority register 10 | MTU1<br>(TGI1A, TGI1B)   | MTU1<br>(TCI1V, TCI1U) | MTU2<br>(TGI2A, TGI2B)   | MTU2<br>(TCI2V, TCI2U)           |
| Interrupt priority register 11 | MTU3<br>(TGI3A to TGI3D) | MTU3<br>(TCI3V)        | MTU4<br>(TGI4A to TGI4D) | MTU4<br>(TCI4V)                  |
| Interrupt priority register 12 | ADC                      | IIC3-0                 | IIC3-1                   | IIC3-2                           |

| Register Name                  | Bits 15 to 12 | Bits 11 to 8 | Bits 7 to 4 | Bits 3 to 0 |
|--------------------------------|---------------|--------------|-------------|-------------|
| Interrupt priority register 13 | IIC3-3        | SCIF0        | SCIF1       | SCIF2       |
| Interrupt priority register 14 | SCIF3         | SSU0         | SSU1        | SSI0        |
| Interrupt priority register 15 | SSI1          | SSI2         | SSI3        | Reserved    |
| Interrupt priority register 16 | FLCTL         | Reserved     | RTC         | RCAN0       |
| Interrupt priority register 17 | RCAN1         | Reserved     | Reserved    | Reserved    |

As shown in table 6.3, by setting the 4-bit groups (bits 15 to 12, bits 11 to 8, bits 7 to 4, and bits 3 to 0) with values from H'0 (0000) to H'F (1111), the priority of each corresponding interrupt is set. Setting of H'0 means priority level 0 (the lowest level) and H'F means priority level 15 (the highest level).

### 6.3.2 Interrupt Control Register 0 (ICR0)

ICR0 is a 16-bit register that sets the input signal detection mode for the external interrupt input pin NMI, and indicates the input level at the NMI pin.

|                |      |    |    |    |    |    |   |      |   |   |   |   |   |   |   |   |
|----------------|------|----|----|----|----|----|---|------|---|---|---|---|---|---|---|---|
| Bit:           | 15   | 14 | 13 | 12 | 11 | 10 | 9 | 8    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                | NMIL | -  | -  | -  | -  | -  | - | NMIE | - | - | - | - | - | - | - | - |
| Initial value: | *    | 0  | 0  | 0  | 0  | 0  | 0 | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           | R    | R  | R  | R  | R  | R  | R | R/W  | R | R | R | R | R | R | R | R |

Note: \* 1 when the NMI pin is high, and 0 when the NMI pin is low.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                   |
|---------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | NMIL     | *             | R   | <p>NMI Input Level</p> <p>Sets the level of the signal input at the NMI pin. The NMI pin level can be obtained by reading this bit. This bit cannot be modified.</p> <p>0: Low level is input to NMI pin</p> <p>1: High level is input to NMI pin</p>                         |
| 14 to 9 | —        | All 0         | R   | <p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>                                                                                                                                                                                   |
| 8       | NMIE     | 0             | R/W | <p>NMI Edge Select</p> <p>Selects whether the falling or rising edge of the interrupt request signal on the NMI pin is detected.</p> <p>0: Interrupt request is detected on falling edge of NMI input</p> <p>1: Interrupt request is detected on rising edge of NMI input</p> |
| 7 to 0  | —        | All 0         | R   | <p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>                                                                                                                                                                                   |

### 6.3.3 Interrupt Control Register 1 (ICR1)

ICR1 is a 16-bit register that specifies the detection mode for external interrupt input pins IRQ7 to IRQ0 individually: low level, falling edge, rising edge, or both edges.

|                |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
|----------------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| Bit:           | 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |

6.3.4 Interrupt Control Register 2 (ICR2)

ICR2 is a 16-bit register that specifies the detection mode for external interrupt input pins PINT7 to PINT0 individually: low level or high level.

6.3.5 IRQ Interrupt Request Register (IRQRR)

IRQRR is a 16-bit register that indicates interrupt requests from external input pins IRQ7 to IRQ0. If edge detection is set for the IRQ7 to IRQ0 interrupts, writing 0 to the IRQ7F to IRQ0F bits after reading IRQ7F to IRQ0F = 1 cancels the retained interrupts.

|     |          |               |     | This bit is always read as 0. The write value should always be 0.                                                                                                          |

### 6.3.9 Bank Number Register (IBNR)

IBNR is a 16-bit register that enables or disables use of register banks and register bank overflow exception. IBNR also indicates the bank number to which saving is performed next through the bits BN3 to BN0.

| 3 to 0  | BN[3:0]  | 0000          | R   | <b>Bank Number</b><br>These bits indicate the bank number to which saving is performed next. When an interrupt using register banks is accepted, saving is performed to the register bank indicated by these bits, and BN is incremented by 1. After BN is decremented by 1 due to execution of a RESBANK (restore from register bank) instruction, restoration from the register bank is performed.          |

## 6.4 Interrupt Sources

There are six types of interrupt sources: NMI, user break, H-UDI, IRQ, PINT, and on-chip peripheral modules. Each interrupt has a priority level (0 to 16), with 0 the lowest and 16 the highest. When set to level 0, that interrupt is masked at all times.

### 6.4.1 NMI Interrupt

The NMI interrupt has a priority level of 16 and is accepted at all times. NMI interrupt requests are edge-detected, and the NMI edge select bit (NMIE) in interrupt control register 0 (ICR0) selects whether the rising edge or falling edge is detected.

Though the priority level of the NMI interrupt is 16, the NMI interrupt exception handling sets the interrupt mask level bits (I3 to I0) in the status register (SR) to level 15.

### 6.4.2 User Break Interrupt

A user break interrupt which occurs when a break condition set in the user break controller (UBC) matches has a priority level of 15. The user break interrupt exception handling sets the I3 to I0 bits in SR to level 15. For user break interrupts, see section 7, User Break Controller (UBC).

### 6.4.3 H-UDI Interrupt

The user debugging interface (H-UDI) interrupt has a priority level of 15, and occurs at serial input of an H-UDI interrupt instruction. H-UDI interrupt requests are edge-detected and retained until they are accepted. The H-UDI interrupt exception handling sets the I3 to I0 bits in SR to level 15. For H-UDI interrupts, see section 29, User Debugging Interface (H-UDI).

### 6.4.4 IRQ Interrupts

IRQ interrupts are input from pins IRQ7 to IRQ0. For the IRQ interrupts, low-level, falling-edge, rising-edge, or both-edge detection can be selected individually for each pin by the IRQ sense select bits (IRQ71S to IRQ01S and IRQ70S to IRQ00S) in interrupt control register 1 (ICR1). The priority level can be set individually in a range from 0 to 15 for each pin by interrupt priority registers 01 and 02 (IPR01 and IPR02).

When using low-level sensing for IRQ interrupts, an interrupt request signal is sent to the INTC while the IRQ7 to IRQ0 pins are low. An interrupt request signal is stopped being sent to the INTC when the IRQ7 to IRQ0 pins are driven high. The status of the interrupt requests can be checked by reading the IRQ interrupt request bits (IRQ7F to IRQ0F) in the IRQ interrupt request register (IRQRR).

When using edge-sensing for IRQ interrupts, an interrupt request is detected due to change of the IRQ7 to IRQ0 pin states, and an interrupt request signal is sent to the INTC. The result of IRQ interrupt request detection is retained until that interrupt request is accepted. Whether IRQ interrupt requests have been detected or not can be checked by reading the IRQ7F to IRQ0F bits in IRQRR. Writing 0 to these bits after reading them as 1 clears the result of IRQ interrupt request detection.

The IRQ interrupt exception handling sets the I3 to I0 bits in SR to the priority level of the accepted IRQ interrupt.

When returning from IRQ interrupt exception service routine, execute the RTE instruction after confirming that the interrupt request has been cleared by the IRQ interrupt request register (IRQRR) so as not to accidentally receive the interrupt request again.

#### 6.4.5 PINT Interrupts

PINT interrupts are input from pins PINT7 to PINT0. Input of the interrupt requests is enabled by the PINT enable bits (PINT7E to PINT0E) in the PINT interrupt enable register (PINTER). For the PINT7 to PINT0 interrupts, low-level or high-level detection can be selected individually for each pin by the PINT sense select bits (PINT7S to PINT0S) in interrupt control register 2 (ICR2). A single priority level in a range from 0 to 15 can be set for all PINT7 to PINT0 interrupts by bits 15 to 12 in interrupt priority register 05 (IPR05).

When using low-level sensing for the PINT7 to PINT0 interrupts, an interrupt request signal is sent to the INTC while the PINT7 to PINT0 pins are low. An interrupt request signal is stopped being sent to the INTC when the PINT7 to PINT0 pins are driven high. The status of the interrupt requests can be checked by reading the PINT interrupt request bits (PINT7R to PINT0R) in the PINT interrupt request register (PIRR). The above description also applies to when using high-level sensing, except for the polarity being reversed. The PINT interrupt exception handling sets the I3 to I0 bits in SR to the priority level of the PINT interrupt.

When returning from IRQ interrupt exception service routine, execute the RTE instruction after confirming that the interrupt request has been cleared by the PINT interrupt request register (PIRR) so as not to accidentally receive the interrupt request again.

### 6.4.6 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts are generated by the following on-chip peripheral modules:

- Direct memory access controller (DMAC)
- USB2.0 host/function module (USB)
- LCD controller (LDC)
- Compare match timer (CMT)
- Bus state controller (BSC)
- Watchdog timer (WDT)
- Multi-function timer pulse unit 2 (MTU2)
- A/D converter (ADC)
- I<sup>2</sup>C bus interface 3 (IIC3)
- Serial communications interface with FIFO (SCIF)
- Synchronous serial communications unit (SSU)
- Serial sound interface (SSI)
- AND/NAND flash memory controller (FLCTL)
- Realtime clock (RTC)
- Controller area network (RCAN-TL1)

As every source is assigned a different interrupt vector, the source does not need to be identified in the exception service routine. A priority level in a range from 0 to 15 can be set for each module by interrupt priority registers 05 to 17 (IPR05 to IPR17). The on-chip peripheral module interrupt exception handling sets the I3 to I0 bits in SR to the priority level of the accepted on-chip peripheral module interrupt.

## 6.5 Interrupt Exception Handling Vector Table and Priority

Table 6.4 lists interrupt sources and their vector numbers, vector table address offsets, and interrupt priorities.

Each interrupt source is allocated a different vector number and vector table address offset. Vector table addresses are calculated from the vector numbers and vector table address offsets. In interrupt exception handling, the interrupt exception service routine start address is fetched from the vector table indicated by the vector table address. For details of calculation of the vector table address, see table 5.4.

The priorities of IRQ interrupts, PINT interrupts, and on-chip peripheral module interrupts can be set freely between 0 and 15 for each pin or module by setting interrupt priority registers 01, 02, and 05 to 17 (IPR01, IPR02, and IPR05 to IPR17). However, if two or more interrupts specified by the same IPR among IPR05 to IPR17 occur, the priorities are defined as shown in the IPR setting unit internal priority of table 6.4, and the priorities cannot be changed. A power-on reset assigns priority level 0 to IRQ interrupts, PINT interrupts, and on-chip peripheral module interrupts. If the same priority level is assigned to two or more interrupt sources and interrupts from those sources occur simultaneously, they are processed by the default priorities indicated in table 6.4.

**Table 6.4 Interrupt Exception Handling Vectors and Priorities**

|                  |  | Interrupt Vector |                             |                                    |                         | IPR Setting Unit  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## 6.6 Operation

### 6.6.1 Interrupt Operation Sequence

The sequence of interrupt operations is described below. Figure 6.2 shows the operation flow.

1. The interrupt request sources send interrupt request signals to the interrupt controller.
2. The interrupt controller selects the highest-priority interrupt from the interrupt requests sent, following the priority levels set in interrupt priority registers 01, 02, and 05 to 17 (IPR01, IPR02, and IPR05 to IPR17). Lower priority interrupts are ignored\*. If two of these interrupts have the same priority level or if multiple interrupts occur within a single IPR, the interrupt with the highest priority is selected, according to the default priority and IPR setting unit internal priority shown in table 6.4.
3. The priority level of the interrupt selected by the interrupt controller is compared with the interrupt level mask bits (I3 to I0) in the status register (SR) of the CPU. If the interrupt request priority level is equal to or less than the level set in bits I3 to I0, the interrupt request is ignored. If the interrupt request priority level is higher than the level in bits I3 to I0, the interrupt controller accepts the interrupt and sends an interrupt request signal to the CPU.
4. When the interrupt controller accepts an interrupt, a low level is output from the  $\overline{\text{IRQOUT}}$  pin.
5. The CPU detects the interrupt request sent from the interrupt controller when the CPU decodes the instruction to be executed. Instead of executing the decoded instruction, the CPU starts interrupt exception handling (figure 6.4).
6. The interrupt exception service routine start address is fetched from the exception handling vector table corresponding to the accepted interrupt.
7. The status register (SR) is saved onto the stack, and the priority level of the accepted interrupt is copied to bits I3 to I0 in SR.
8. The program counter (PC) is saved onto the stack.
9. The CPU jumps to the fetched interrupt exception service routine start address and starts executing the program. The jump that occurs is not a delayed branch.
10. A high level is output from the  $\overline{\text{IRQOUT}}$  pin. However, if the interrupt controller accepts an interrupt with a higher priority than the interrupt just being accepted, the  $\overline{\text{IRQOUT}}$  pin holds low level.

Notes: The interrupt source flag should be cleared in the interrupt handler. After clearing the interrupt source flag, "time from occurrence of interrupt request until interrupt controller identifies priority, compares it with mask bits in SR, and sends interrupt request signal to CPU" shown in table 6.5 is required before the interrupt source sent to the CPU is actually cancelled. To ensure that an interrupt request that should have been cleared is not inadvertently accepted again, read the interrupt source flag after it has been cleared, and then execute an RTE instruction.

- \* Interrupt requests that are designated as edge-sensing are held pending until the interrupt requests are accepted. IRQ interrupts, however, can be cancelled by accessing the IRQ interrupt request register (IRQRR). For details, see section 6.4.4, IRQ Interrupts.

Interrupts held pending due to edge-sensing are cleared by a power-on reset.

### Figure 6.2 Interrupt Operation Flow

### 6.6.2 Stack after Interrupt Exception Handling

Figure 6.3 shows the stack after interrupt exception handling.

**Figure 6.3 Stack after Interrupt Exception Handling**

## 6.7 Interrupt Response Time

Table 6.5 lists the interrupt response time, which is the time from the occurrence of an interrupt request until the interrupt exception handling starts and fetching of the first instruction in the exception service routine begins. The interrupt processing operations differ in the cases when banking is disabled, when banking is enabled without register bank overflow, and when banking is enabled with register bank overflow. Figures 6.4 and 6.5 show examples of pipeline operation when banking is disabled. Figures 6.6 and 6.7 show examples of pipeline operation when banking is enabled without register bank overflow. Figures 6.8 and 6.9 show examples of pipeline operation when banking is enabled with register bank overflow.

**Table 6.5 Interrupt Response Time**

Notes: m1 to m4 are the number of states needed for the following memory accesses.

m1: Vector address read (longword read)

m2: SR save (longword write)

m3: PC save (longword write)

m4: Banked registers (R0 to R14, GBR, MACH, MACL, and PR) are restored from the stack.

1. In the case that m1 = m2 = m3 = m4 = 1  $l_{cyc}$ .

2. In the case that ( $I\phi$ ,  $B\phi$ ,  $P\phi$ ) = (200 MHz, 66 MHz, 33 MHz).

## 6.8 Register Banks

This LSI has fifteen register banks used to perform register saving and restoration required in the interrupt processing at high speed. Figure 6.10 shows the register bank configuration.

**Figure 6.10 Overview of Register Bank Configuration**

## 6.8.1 Banked Register and Input/Output of Banks

### (1) Banked Register

The contents of the general registers (R0 to R14), global base register (GBR), multiply and accumulate registers (MACH and MACL), and procedure register (PR), and the vector table address offset are banked.

### (2) Input/Output of Banks

This LSI has fifteen register banks, bank 0 to bank 14. Register banks are stacked in first-in last-out (FILO) sequence. Saving takes place in order, beginning from bank 0, and restoration takes place in the reverse order, beginning from the last bank saved to.

## 6.8.2 Bank Save and Restore Operations

### (1) Saving to Bank

Figure 6.11 shows register bank save operations. The following operations are performed when an interrupt for which usage of register banks is allowed is accepted by the CPU:

- Assume that the bank number bit value in the bank number register (IBNR), BN, is  $i$  before the interrupt is generated.
- The contents of registers R0 to R14, GBR, MACH, MACL, and PR, and the interrupt vector table address offset (VTO) of the accepted interrupt are saved in the bank indicated by BN, bank  $i$ .
- The BN value is incremented by 1.

**Figure 6.11 Bank Save Operations**

Figure 6.12 shows the timing for saving to a register bank. Saving to a register bank takes place between the start of interrupt exception handling and the start of fetching the first instruction in the interrupt exception service routine.

**Figure 6.12 Bank Save Timing**

## (2) Restoration from Bank

The RESBANK (restore from register bank) instruction is used to restore data saved in a register bank. After restoring data from the register banks with the RESBANK instruction at the end of the interrupt exception service routine, execute the RTE instruction to return from interrupt exception service routine.

### 6.8.3 Save and Restore Operations after Saving to All Banks

If an interrupt occurs and usage of the register banks is enabled for the interrupt accepted by the CPU in a state where saving has been performed to all register banks, automatic saving to the stack is performed instead of register bank saving if the BOVE bit in the bank number register (IBNR) is cleared to 0. If the BOVE bit in IBNR is set to 1, register bank overflow exception occurs and data is not saved to the stack.

Save and restore operations when using the stack are as follows:

#### (1) Saving to Stack

1. The status register (SR) and program counter (PC) are saved to the stack during interrupt exception handling.
2. The contents of the banked registers (R0 to R14, GBR, MACH, MACL, and PR) are saved to the stack. The registers are saved to the stack in the order of MACL, MACH, GBR, PR, R14, R13, ..., R1, and R0.
3. The register bank overflow bit (BO) in SR is set to 1.
4. The bank number bit (BN) value in the bank number register (IBNR) remains set to the maximum value of 15.

#### (2) Restoration from Stack

When the RESBANK (restore from register bank) instruction is executed with the register bank overflow bit (BO) in SR set to 1, the CPU operates as follows:

1. The contents of the banked registers (R0 to R14, GBR, MACH, MACL, and PR) are restored from the stack. The registers are restored from the stack in the order of R0, R1, ..., R13, R14, PR, GBR, MACH, and MACL.
2. The bank number bit (BN) value in the bank number register (IBNR) remains set to the maximum value of 15.

### 6.8.4 Register Bank Exception

There are two register bank exceptions (register bank errors): register bank overflow and register bank underflow.

#### (1) Register Bank Overflow

This exception occurs if, after data has been saved to all of the register banks, an interrupt for which register bank use is allowed is accepted by the CPU, and the BOVE bit in the bank number register (IBNR) is set to 1. In this case, the bank number bit (BN) value in the bank number register (IBNR) remains set to the bank count of 15 and saving is not performed to the register bank.

#### (2) Register Bank Underflow

This exception occurs if the RESBANK (restore from register bank) instruction is executed when no data has been saved to the register banks. In this case, the values of R0 to R14, GBR, MACH, MACL, and PR do not change. In addition, the bank number bit (BN) value in the bank number register (IBNR) remains set to 0.

### 6.8.5 Register Bank Error Exception Handling

When a register bank error occurs, register bank error exception handling starts. When this happens, the CPU operates as follows:

1. The exception service routine start address which corresponds to the register bank error that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the last executed instruction for a register bank overflow, and the start address of the executed RESBANK instruction for a register bank underflow. To prevent multiple interrupts from occurring at a register bank overflow, the interrupt priority level that caused the register bank overflow is written to the interrupt mask level bits (I3 to I0) of the status register (SR).
4. Program execution starts from the exception service routine start address.

## 6.9 Data Transfer with Interrupt Request Signals

Interrupt request signals can be used to activate the DMAC and transfer data.

Interrupt sources that are designated to activate the DMAC are masked without being input to the INTC. The mask condition is as follows:

$$\begin{aligned} \text{Mask condition} = & \text{DME} \bullet (\text{DE0} \bullet \text{interrupt source select 0} + \text{DE1} \bullet \text{interrupt source select 1} \\ & + \text{DE2} \bullet \text{interrupt source select 2} + \text{DE3} \bullet \text{interrupt source select 3} + \\ & \text{DE4} \bullet \text{interrupt source select 4} + \text{DE5} \bullet \text{interrupt source select 5} + \text{DE6} \\ & \bullet \text{interrupt source select 6} + \text{DE7} \bullet \text{interrupt source select 7}) \end{aligned}$$

Figure 6.13 shows a block diagram of interrupt control.

Here, DME is bit 0 in DMAOR of the DMAC, and DEN (n = 0 to 7) is bit 0 in CHCR0 to CHCR7 of the DMAC. For details, see section 10, Direct Memory Access Controller (DMAC).

**Figure 6.13 Interrupt Control Block Diagram**

### **6.9.1 Handling Interrupt Request Signals as Sources for CPU Interrupt but Not DMAC Activating**

- 1 Do not select DMAC activating sources or clear the DME bit to 0. If, DMAC activating sources are selected, clear the DE bit to 0 for the relevant channel of the DMAC.
2. When interrupts occur, interrupt requests are sent to the CPU.
3. The CPU clears the interrupt source and performs the necessary processing in the interrupt exception service routine.

### **6.9.2 Handling Interrupt Request Signals as Sources for Activating DMAC but Not CPU Interrupt**

1. Select DMAC activating sources and set both the DE and DME bits to 1. This masks CPU interrupt sources regardless of the interrupt priority register settings.
2. Activating sources are applied to the DMAC when interrupts occur.
3. The DMAC clears the interrupt sources when starting transfer.

## 6.10 Usage Note

### 6.10.1 Timing to Clear an Interrupt Source

The interrupt source flags should be cleared in the interrupt exception service routine. After clearing the interrupt source flag, "time from occurrence of interrupt request until interrupt controller identifies priority, compares it with mask bits in SR, and sends interrupt request signal to CPU" shown in table 6.5 is required before the interrupt source sent to the CPU is actually cancelled. To ensure that an interrupt request that should have been cleared is not inadvertently accepted again, read\* the interrupt source flag after it has been cleared, and then execute an RTE instruction.

Note: \* When clearing the USB interrupt source flag, read the flag three times after clearing it.

### 6.10.2 Timing of $\overline{\text{IRQOUT}}$ Negation

Once the interrupt controller has accepted an interrupt request, the low level is output from the  $\overline{\text{IRQOUT}}$  pin until the CPU jumps to the first address of the interrupt exception service routine, after which the high level is output from the  $\overline{\text{IRQOUT}}$  pin.

If, however, the interrupt controller has accepted an interrupt request and the low level is being output from the  $\overline{\text{IRQOUT}}$  pin, but the interrupt request is canceled before the CPU has jumped to the first address of the interrupt exception service routine, the low level continues to be output from the  $\overline{\text{IRQOUT}}$  pin until the CPU has jumped to the first address of the interrupt exception service routine for the next interrupt request.

## Section 7 User Break Controller (UBC)

The user break controller (UBC) provides functions that simplify program debugging. These functions make it easy to design an effective self-monitoring debugger, enabling the chip to debug programs without using an in-circuit emulator. Instruction fetch or data read/write (bus cycle (CPU or DMAC) selection in the case of data read/write), data size, data contents, address value, and stop timing in the case of instruction fetch are break conditions that can be set in the UBC. Since this LSI uses a Harvard architecture, instruction fetch on the CPU bus (C bus) is performed by issuing bus cycles on the instruction fetch bus (F bus), and data access on the C bus is performed by issuing bus cycles on the memory access bus (M bus). The internal bus (I bus) consists of the internal CPU bus, on which the CPU issues bus cycles, and the internal DMA bus, on which the DMA issues bus cycles. The UBC monitors the C bus and I bus.

### 7.1 Features

1. The following break comparison conditions can be set.

Number of break channels: two channels (channels 0 and 1)

User break can be requested as the independent condition on channels 0 and 1.

— Address

Comparison of the 32-bit address is maskable in 1-bit units.

One of the four address buses (F address bus (FAB), M address bus (MAB), internal CPU address bus (ICAB), and internal DMA address bus (IDAB)) can be selected.

— Data

Comparison of the 32-bit data is maskable in 1-bit units.

One of the three data buses (M data bus (MDB), internal CPU data bus (ICDB), and internal DMA data bus (IDDB)) can be selected.

— Bus selection when I bus is selected

Internal CPU bus or internal DMA bus

— Bus cycle

Instruction fetch (only when C bus is selected) or data access

— Read/write

— Operand size

Byte, word, and longword

2. In an instruction fetch cycle, it can be selected whether the start of user break interrupt exception processing is set before or after an instruction is executed.
3. When a break condition is satisfied, a trigger signal is output from the  $\overline{\text{UBCTR}}\text{G}$  pin.

Figure 7.1 shows a block diagram of the UBC.

**Figure 7.1 Block Diagram of UBC**

## 7.2 Input/Output Pin

Table 7.1 shows the pin configuration of the UBC.

**Table 7.1 Pin Configuration**

| Pin Name    | Symbol | I/O    | Function                                                                             |
|-------------|--------|--------|--------------------------------------------------------------------------------------|
| UBC trigger | UBCTRG | Output | Indicates that a setting condition is satisfied on either channel 0 or 1 of the UBC. |

## 7.3 Register Descriptions

The UBC has the following registers. Five control registers for each channel and one common control register for channel 0 and channel 1 are available. A register for each channel is described as BAR\_0 for the BAR register in channel 0.

**Table 7.2 Register Configuration**

| Channel | Register Name                 | Abbrevia-<br>tion | R/W | Initial Value | Address    | Access<br>Size |
|---------|-------------------------------|-------------------|-----|---------------|------------|----------------|
| 0       | Break address register_0      | BAR_0             | R/W | H'00000000    | H'FFFC0400 | 32             |
|         | Break address mask register_0 | BAMR_0            | R/W | H'00000000    | H'FFFC0404 | 32             |
|         | Break bus cycle register_0    | BBR_0             | R/W | H'0000        | H'FFFC04A0 | 16             |
|         | Break data register_0         | BDR_0             | R/W | H'00000000    | H'FFFC0408 | 32             |
|         | Break data mask register_0    | BDMR_0            | R/W | H'00000000    | H'FFFC040C | 32             |
| 1       | Break address register_1      | BAR_1             | R/W | H'00000000    | H'FFFC0410 | 32             |
|         | Break address mask register_1 | BAMR_1            | R/W | H'00000000    | H'FFFC0414 | 32             |
|         | Break bus cycle register_1    | BBR_1             | R/W | H'0000        | H'FFFC04B0 | 16             |
|         | Break data register_1         | BDR_1             | R/W | H'00000000    | H'FFFC0418 | 32             |
|         | Break data mask register_1    | BDMR_1            | R/W | H'00000000    | H'FFFC041C | 32             |
| Common  | Break control register        | BRCR              | R/W | H'00000000    | H'FFFC04C0 | 32             |

### 7.3.1 Break Address Register (BAR)

BAR is a 32-bit readable/writable register. BAR specifies the address used as a break condition in each channel. The control bits CD[1:0] and CP[1:0] in the break bus cycle register (BBR) select one of the four address buses for a break condition.

|                |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Bit:           | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
|                | BA31 | BA30 | BA29 | BA28 | BA27 | BA26 | BA25 | BA24 | BA23 | BA22 | BA21 | BA20 | BA19 | BA18 | BA17 | BA16 |
| Initial value: | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |
| R/W:           | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |

|                |      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |     |
|----------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15   | 14   | 13   | 12   | 11   | 10   | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                | BA15 | BA14 | BA13 | BA12 | BA11 | BA10 | BA9 | BA8 | BA7 | BA6 | BA5 | BA4 | BA3 | BA2 | BA1 | BA0 |
| Initial value: | 0    | 0    | 0    | 0    | 0    | 0    | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| R/W:           | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit     | Bit Name    | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|-------------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BA31 to BA0 | All 0         | R/W | <p>Break Address</p> <p>Store an address on the CPU address bus (FAB or MAB) or internal address bus (ICAB or IDAB) specifying break conditions.</p> <p>When the C bus and instruction fetch cycle are selected by BBR, specify an FAB address in bits BA31 to BA0.</p> <p>When the C bus and data access cycle are selected by BBR, specify an MAB address in bits BA31 to BA0.</p> <p>When the internal CPU bus (I bus) is selected by BBR, specify an ICAB address in bits BA31 to BA0.</p> <p>When the internal DMA bus (I bus) is selected by BBR, specify an IDAB address in bits BA31 to BA0.</p> |

Note: When setting the instruction fetch cycle as a break condition, clear the LSB in BAR to 0.

7.3.2 Break Address Mask Register (BAMR)

BAMR is a 32-bit readable/writable register. BAMR specifies bits masked in the break address bits specified by BAR.

|                |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Bit:           | 31    | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |
|                | BAM31 | BAM30 | BAM29 | BAM28 | BAM27 | BAM26 | BAM25 | BAM24 | BAM23 | BAM22 | BAM21 | BAM20 | BAM19 | BAM18 | BAM17 | BAM16 |
| Initial value: | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |
| R/W:           | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |

|                |       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|----------------|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| Bit:           | 15    | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

### 7.3.3 Break Data Register (BDR)

BDR is a 32-bit readable/writable register. The control bits CD[1:0] and CP[1:0] in the break bus cycle register (BBR) select one of the three data buses for a break condition.

|                |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Bit:           | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
|                | BD31 | BD30 | BD29 | BD28 | BD27 | BD26 | BD25 | BD24 | BD23 | BD22 | BD21 | BD20 | BD19 | BD18 | BD17 | BD16 |
| Initial value: | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |
| R/W:           | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |

|                |      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |     |
|----------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

|---------|-------------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BD31 to BD0 | All 0         | R/W | <p>Break Data Bits</p> <p>Store data which specifies a break condition.</p> <p>When the C bus is selected by BBR, specify the break data on MDB in bits BD31 to BD0.</p> <p>When the internal CPU bus (I bus) is selected by BBR, specify an ICDB address in bits BD31 to BD0.</p> <p>When the internal DMA bus (I bus) is selected by BBR, specify an IDDB address in bits BD31 to BD0.</p> |

- Notes:
1. Set the operand size when specifying a value on a data bus as the break condition.
  2. When the byte size is selected as a break condition, the same byte data must be set in bits 31 to 24, 23 to 16, 15 to 8, and 7 to 0 in BDR as the break data. Similarly, when the word size is selected, the same word data must be set in bits 31 to 16 and 15 to 0.

7.3.4 Break Data Mask Register (BDMR)

BDMR is a 32-bit readable/writable register. BDMR specifies bits masked in the break data bits specified by BDR.

| Bit     | Bit Name      | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                          |
|---------|---------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BDM31 to BDM0 | All 0         | R/W | <div>Break Data Mask</div> <div>Specify bits masked in the break data bits specified by BDR (BD31 to BD0).</div> <div>0: Break data bit BDn is included in the break condition</div> <div>1: Break data bit BDn is masked and not included in the break condition</div> <div>Note: n = 31 to 0</div> |

- Notes:
1. Set the operand size when specifying a value on a data bus as the break condition.

2. When the byte size is selected as a break condition, the same byte data must be set in bits 31 to 24, 23 to 16, 15 to 8, and 7 to 0 in BDMR as the break mask data. Similarly, when the word size is selected, the same word data must be set in bits 31 to 16 and 15 to 0.

### 7.3.5 Break Bus Cycle Register (BBR)

BBR is a 16-bit readable/writable register, which specifies (1) disabling or enabling of user break interrupt requests, (2) including or excluding of the data bus value, (3) internal CPU bus or internal DMA bus, (4) C bus cycle or I bus cycle, (5) instruction fetch or data access, (6) read or write, and (7) operand size as the break conditions.

### 7.3.6 Break Control Register (BRCR)

BRCR sets the following conditions:

1. Specifies whether a start of user break interrupt exception processing by instruction fetch cycle is set before or after instruction execution.
2. Specifies the pulse width of the  $\overline{\text{UBCTR}}\overline{\text{G}}$  output when a break condition is satisfied.
3. Specifies whether a trigger signal is output to the  $\overline{\text{UBCTR}}\overline{\text{G}}$  pin when a break condition is satisfied.

BRCR is a 32-bit readable/writable register that has break condition match flags and bits for setting other break conditions. For the condition match flags of bits 15 to 12, writing 1 is invalid (previous values are retained) and writing 0 is only possible. To clear the flag, write 0 to the flag bit to be cleared and 1 to all other flag bits.

## 7.4 Operation

### 7.4.1 Flow of the User Break Operation

The flow from setting of break conditions to user break interrupt exception handling is described below:

1. The break address is set in a break address register (BAR). The masked address bits are set in a break address mask register (BAMR). The break data is set in the break data register (BDR). The masked data bits are set in the break data mask register (BDMR). The bus break conditions are set in the break bus cycle register (BBR). Three control bit groups of BBR (C bus cycle/I bus cycle select, instruction fetch/data access select, and read/write select) are each set. No user break will be generated if even one of these groups is set to 00. The relevant break control conditions are set in the bits of the break control register (BRCR). Make sure to set all registers related to breaks before setting BBR, and branch after reading from the last written register. The newly written register values become valid from the instruction at the branch destination.
2. In the case where the break conditions are satisfied and the user break interrupt request is enabled, the UBC sends a user break interrupt request to the INTC, sets the C bus condition match flag (SCMFC) or I bus condition match flag (SCMFD) for the appropriate channel, and outputs a pulse to the  $\overline{\text{UBCTRG}}$  pin with the width set by the CKS[1:0] bits. Setting the UBID bit in BBR to 1 enables external monitoring of the trigger output without requesting user break interrupts.
3. On receiving a user break interrupt request signal, the INTC determines its priority. Since the user break interrupt has a priority level of 15, it is accepted when the priority level set in the interrupt mask level bits (I3 to I0) of the status register (SR) is 14 or lower. If the I3 to I0 bits are set to a priority level of 15, the user break interrupt is not accepted, but the conditions are checked, and condition match flags are set if the conditions match. For details on ascertaining the priority, see section 6, Interrupt Controller (INTC).
4. Condition match flags (SCMFC and SCMFD) can be used to check which condition has been satisfied. Clear the condition match flags during the user break interrupt exception processing routine. The interrupt occurs again if this operation is not performed.
5. There is a chance that the break set in channel 0 and the break set in channel 1 occur around the same time. In this case, there will be only one user break request to the INTC, but these two break channel match flags may both be set.
6. When selecting the I bus as the break condition, note as follows:
  - Whether or not an access issued on the C bus by the CPU is issued on the internal CPU bus depends on the cache settings. Regarding the I bus operation under cache conditions, see table 8.8.

- When a break condition is specified for the I bus, only the data access cycle is monitored. The instruction fetch cycle (including the cache renewal cycle) is not monitored.
- Only data access cycles are issued for the internal DMA bus cycles.
- If a break condition is specified for the I bus, even when the condition matches in an internal CPU bus cycle resulting from an instruction executed by the CPU, at which instruction the user break interrupt request is to be accepted cannot be clearly defined.

#### 7.4.2 Break on Instruction Fetch Cycle

1. When C bus/instruction fetch/read/word or longword is set in the break bus cycle register (BBR), the break condition is the FAB bus instruction fetch cycle. Whether a start of user break interrupt exception processing is set before or after the execution of the instruction can then be selected with the PCB0 or PCB1 bit of the break control register (BRCR) for the appropriate channel. If an instruction fetch cycle is set as a break condition, clear BA0 bit in the break address register (BAR) to 0. A break cannot be generated as long as this bit is set to 1.
2. A break for instruction fetch which is set as a break before instruction execution occurs when it is confirmed that the instruction has been fetched and will be executed. This means a break does not occur for instructions fetched by overrun (instructions fetched at a branch or during an interrupt transition, but not to be executed). When this kind of break is set for the delay slot of a delayed branch instruction, the user break interrupt request is not received until the execution of the first instruction at the branch destination.

Note: If a branch does not occur at a delayed branch instruction, the subsequent instruction is not recognized as a delay slot.

3. When setting a break condition for break after instruction execution, the instruction set with the break condition is executed and then the break is generated prior to execution of the next instruction. As with pre-execution breaks, a break does not occur with overrun fetch instructions. When this kind of break is set for a delayed branch instruction and its delay slot, the user break interrupt request is not received until the first instruction at the branch destination.
4. When an instruction fetch cycle is set, the break data register (BDR) is ignored. Therefore, break data cannot be set for the break of the instruction fetch cycle.
5. If the I bus is set for a break of an instruction fetch cycle, the setting is invalidated.

### 7.4.3 Break on Data Access Cycle

1. If the C bus is specified as a break condition for data access break, condition comparison is performed for the addresses (and data) accessed by the executed instructions, and a break occurs if the condition is satisfied. If the I bus is specified as a break condition, condition comparison is performed for the addresses (and data) of the data access cycles on the bus specified by the I bus select bits, and a break occurs if the condition is satisfied. For details on the CPU bus cycles issued on the internal CPU bus, see 6 in section 7.4.1, Flow of the User Break Operation.
2. The relationship between the data access cycle address and the comparison condition for each operand size is listed in table 7.3.

**Table 7.3 Data Access Cycle Addresses and Operand Size Comparison Conditions**

| Access Size | Address Compared                                                         |
|-------------|--------------------------------------------------------------------------|
| Longword    | Compares break address register bits 31 to 2 to address bus bits 31 to 2 |
| Word        | Compares break address register bits 31 to 1 to address bus bits 31 to 1 |
| Byte        | Compares break address register bits 31 to 0 to address bus bits 31 to 0 |

This means that when address H'00001003 is set in the break address register (BAR), for example, the bus cycle in which the break condition is satisfied is as follows (where other conditions are met).

Longword access at H'00001000

Word access at H'00001002

Byte access at H'00001003

3. When the data value is included in the break conditions:  
When the data value is included in the break conditions, either longword, word, or byte is specified as the operand size in the break bus cycle register (BBR). When data values are included in break conditions, a break is generated when the address conditions and data conditions both match. To specify byte data for this case, set the same data in the four bytes at bits 31 to 24, 23 to 16, 15 to 8, and 7 to 0 of the break data register (BDR) and break data mask register (BDMR). To specify word data for this case, set the same data in the two words at bits 31 to 16 and 15 to 0.
4. Access by a PREF instruction is handled as read access in longword units without access data. Therefore, if including the value of the data bus when a PREF instruction is specified as a break condition, a break will not occur.
5. If the data access cycle is selected, the instruction at which the break will occur cannot be determined.

#### 7.4.4 Value of Saved Program Counter

When a user break interrupt request is received, the address of the instruction from where execution is to be resumed is saved to the stack, and the exception handling state is entered. If the C bus (FAB)/instruction fetch cycle is specified as a break condition, the instruction at which the break should occur can be uniquely determined. If the C bus/data access cycle or I bus/data access cycle is specified as a break condition, the instruction at which the break should occur cannot be uniquely determined.

1. When C bus (FAB)/instruction fetch (before instruction execution) is specified as a break condition:

The address of the instruction that matched the break condition is saved to the stack. The instruction that matched the condition is not executed, and the break occurs before it. However when a delay slot instruction matches the condition, the instruction is executed, and the branch destination address is saved to the stack.

2. When C bus (FAB)/instruction fetch (after instruction execution) is specified as a break condition:

The address of the instruction following the instruction that matched the break condition is saved to the stack. The instruction that matches the condition is executed, and the break occurs before the next instruction is executed. However when a delayed branch instruction or delay slot matches the condition, the instruction is executed, and the branch destination address is saved to the stack.

3. When C bus/data access cycle or I bus/data access cycle is specified as a break condition:

The address after executing several instructions of the instruction that matched the break condition is saved to the stack.

### 7.4.5 Usage Examples

#### (1) Break Condition Specified for C Bus Instruction Fetch Cycle

(Example 1-1)

- Register specifications

BAR\_0 = H'00000404, BAMR\_0 = H'00000000, BBR\_0 = H'0054, BAR\_1 = H'00008010,  
BAMR\_1 = H'00000006, BBR\_1 = H'0054, BDR\_1 = H'00000000, BDMR\_1 = H'00000000,  
BRCR = H'00000020

<Channel 0>

Address: H'00000404, Address mask: H'00000000

Bus cycle: C bus/instruction fetch (after instruction execution)/read (operand size is not included in the condition)

<Channel 1>

Address: H'00008010, Address mask: H'00000006

Data: H'00000000, Data mask: H'00000000

Bus cycle: C bus/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

A user break occurs after an instruction of address H'00000404 is executed or before instructions of addresses H'00008010 to H'00008016 are executed.

(Example 1-2)

- Register specifications

BAR\_0 = H'00027128, BAMR\_0 = H'00000000, BBR\_0 = H'005A, BAR\_1 = H'00031415,  
BAMR\_1 = H'00000000, BBR\_1 = H'0054, BDR\_1 = H'00000000, BDMR\_1 = H'00000000,  
BRCR = H'00000000

<Channel 0>

Address: H'00027128, Address mask: H'00000000

Bus cycle: C bus/instruction fetch (before instruction execution)/write/word

<Channel 1>

Address: H'00031415, Address mask: H'00000000

Data: H'00000000, Data mask: H'00000000

Bus cycle: C bus/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

On channel 0, a user break does not occur since instruction fetch is not a write cycle. On channel 1, a user break does not occur since instruction fetch is performed for an even address.

(Example 1-3)

- Register specifications

BAR\_0 = H'00008404, BAMR\_0 = H'00000FFF, BBR\_0 = H'0054, BAR\_1 = H'00008010,  
BAMR\_1 = H'00000006, BBR\_1 = H'0054, BDR\_1 = H'00000000, BDMR\_1 = H'00000000,  
BRCR = H'00000020

<Channel 0>

Address: H'00008404, Address mask: H'00000FFF

Bus cycle: C bus/instruction fetch (after instruction execution)/read (operand size is not included in the condition)

<Channel 1>

Address: H'00008010, Address mask: H'00000006

Data: H'00000000, Data mask: H'00000000

Bus cycle: C bus/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

A user break occurs after an instruction with addresses H'00008000 to H'00008FFE is executed or before an instruction with addresses H'00008010 to H'00008016 are executed.

## (2) Break Condition Specified for C Bus Data Access Cycle

(Example 2-1)

- Register specifications

BAR\_0 = H'00123456, BAMR\_0 = H'00000000, BBR\_0 = H'0064, BAR\_1 = H'000ABCDE,  
BAMR\_1 = H'000000FF, BBR\_1 = H'106A, BDR\_1 = H'A512A512,  
BDMR\_1 = H'00000000, BRCR = H'00000000

<Channel 0>

Address: H'00123456, Address mask: H'00000000

Bus cycle: C bus/data access/read (operand size is not included in the condition)

<Channel 1>

Address: H'000ABCDE, Address mask: H'000000FF

Data: H'0000A512, Data mask: H'00000000

Bus cycle: C bus/data access/write/word

On channel 0, a user break occurs with longword read from address H'00123456, word read from address H'00123456, or byte read from address H'00123456. On channel 1, a user break occurs when word H'A512 is written in addresses H'000ABC00 to H'000ABCFE.

### (3) Break Condition Specified for I Bus Data Access Cycle

(Example 3-1)

- Register specifications

BAR\_0 = H'00314156, BAMR\_0 = H'00000000, BBR\_0 = H'0194, BAR\_1 = H'00055555,  
BAMR\_1 = H'00000000, BBR\_1 = H'12A9, BDR\_1 = H'78787878, BDMR\_1 = H'0F0F0F0F,  
BRCR = H'00000000

<Channel 0>

Address: H'00314156, Address mask: H'00000000

Bus cycle: Internal CPU bus/instruction fetch/read (operand size is not included in the condition)

<Channel 1>

Address: H'00055555, Address mask: H'00000000

Data: H'00000078, Data mask: H'0000000F

Bus cycle: Internal DMA bus/data access/write/byte

On channel 0, the setting of the internal CPU bus/instruction fetch is ignored.

On channel 1, a user break occurs when the DMAC writes byte data H'7x in address H'00055555 on the internal DMA bus (access via the internal CPU bus does not generate a user break).

## 7.5 Usage Notes

1. The CPU can read from or write to the UBC registers via the internal CPU bus. Accordingly, during the period from executing an instruction to rewrite the UBC register till the new value is actually rewritten, the desired break may not occur. In order to know the timing when the UBC register is changed, read from the last written register. Instructions after then are valid for the newly written register value.
2. The UBC cannot monitor the C bus, internal CPU, and internal DMA bus cycles in the same channel.
3. When a user break interrupt request and another exception source occur at the same instruction, which has higher priority is determined according to the priority levels defined in table 5.1 in section 5, Exception Handling. If an exception source with higher priority occurs, the user break interrupt request is not received.
4. Note the following when a break occurs in a delay slot.

If a pre-execution break is set at a delay slot instruction, the user break interrupt request is not received immediately before execution of the branch destination.
5. User breaks are disabled during UBC module standby mode. Do not read from or write to the UBC registers during UBC module standby mode; the values are not guaranteed.
6. Do not set an address within an interrupt exception handling routine whose interrupt priority level is at least 15 (including user break interrupts) as a break address.
7. Do not set break after instruction execution for the SLEEP instruction or for the delayed branch instruction where the SLEEP instruction is placed at its delay slot.
8. When setting a break for a 32-bit instruction, set the address where the upper 16 bits are placed. If the address of the lower 16 bits is set and a break before instruction execution is set as a break condition, the break is handled as a break after instruction execution.
9. Do not set a user break before instruction execution for the instruction following the DIVU or DIVS instruction. If a user break before instruction execution is set for the instruction following the DIVU or DIVS instruction and an exception or interrupt occurs during execution of the DIVU or DIVS instruction, a user break occurs before instruction execution even though execution of the DIVU or DIVS instruction is halted.

## Section 8 Cache

### 8.1 Features

- Capacity  
Instruction cache: 8 Kbytes  
Operand cache: 8 Kbytes
- Structure: Instructions/data separated, 4-way set associative
- Way lock function (operand cache only): Way 2 and way 3 are lockable
- Line size: 16 bytes
- Number of entries: 128 entries/way
- Write system: Write-back/write-through selectable
- Replacement method: Least-recently-used (LRU) algorithm

#### 8.1.1 Cache Structure

The cache separates data and instructions and uses a 4-way set associative system. It is composed of four ways (banks), each of which is divided into an address section and a data section.

Each of the address and data sections is divided into 128 entries per way. The data section of the entry is called a line. Each line consists of 16 bytes (4 bytes  $\times$  4). The data capacity per way is 2 Kbytes (16 bytes  $\times$  128 entries), with a total of 8 Kbytes in the cache as a whole (4 ways). Figure 8.1 shows the operand cache structure. The instruction cache structure is the same as the operand cache structure except for not having the U bit.

**Figure 8.1 Operand Cache Structure**

### (1) Address Array

The V bit indicates whether the entry data is valid. When the V bit is 1, data is valid; when 0, data is not valid.

The U bit (only for operand cache) indicates whether the entry has been written to in write-back mode. When the U bit is 1, the entry has been written to; when 0, it has not.

The tag address holds the physical address used in the external memory access. It consists of 21 bits (address bits 31 to 11) used for comparison during cache searches. In this LSI, the addresses of the cache-enabled space are H'00000000 to H'1FFFFFFF (see section 9, Bus State Controller (BSC)), and therefore the upper three bits of the tag address are cleared to 0.

The V and U bits are initialized to 0 by a power-on reset but not initialized by a manual reset or in software standby mode. The tag address is not initialized by a power-on reset or manual reset or in software standby mode.

### (2) Data Array

Holds a 16-byte instruction or data. Entries are registered in the cache in line units (16 bytes).

The data array is not initialized by a power-on reset or manual reset or in software standby mode.

### (3) LRU

With the 4-way set associative system, up to four instructions or data with the same entry address can be registered in the cache. When an entry is registered, LRU shows which of the four ways it is recorded in. There are six LRU bits, controlled by hardware. A least-recently-used (LRU) algorithm is used to select the way that has been least recently accessed.

Six LRU bits indicate the way to be replaced in case of a cache miss. The relationship between LRU and way replacement is shown in table 8.1 when the cache lock function (only for operand cache) is not used (concerning the case where the cache lock function is used, see section 8.2.2, Cache Control Register 2 (CCR2)). If a bit pattern other than those listed in table 8.1 is set in the LRU bits by software, the cache will not function correctly. When modifying the LRU bits by software, set one of the patterns listed in table 8.1.

The LRU bits are initialized to B'000000 by a power-on reset but not initialized by a manual reset or in software standby mode.

**Table 8.1 LRU and Way Replacement (Cache Lock Function Not Used)**

| <b>LRU (Bits 5 to 0)</b>                       | <b>Way to be Replaced</b> |
|------------------------------------------------|---------------------------|
| 000000, 000100, 010100, 100000, 110000, 110100 | 3                         |
| 000001, 000011, 001011, 100001, 101001, 101011 | 2                         |
| 000110, 000111, 001111, 010110, 011110, 011111 | 1                         |
| 111000, 111001, 111011, 111100, 111110, 111111 | 0                         |

## 8.2 Register Descriptions

The cache has the following registers.

**Table 8.2 Register Configuration**

| Register Name            | Abbreviation | R/W | Initial Value | Address    | Access Size |
|--------------------------|--------------|-----|---------------|------------|-------------|
| Cache control register 1 | CCR1         | R/W | H'00000000    | H'FFFC1000 | 32          |
| Cache control register 2 | CCR2         | R/W | H'00000000    | H'FFFC1004 | 32          |

### 8.2.1 Cache Control Register 1 (CCR1)

The instruction cache is enabled or disabled using the ICE bit. The ICF bit controls disabling of all instruction cache entries. The operand cache is enabled or disabled using the OCE bit. The OCF bit controls disabling of all operand cache entries. The WT bit selects either write-through mode or write-back mode for operand cache.

Programs that change the contents of CCR1 should be placed in a cache-disabled space, and a cache-enabled space should be accessed after reading the contents of CCR1.

## 8.2.2 Cache Control Register 2 (CCR2)

CCR2 is used to enable or disable the cache locking function for operand cache and is valid in cache locking mode only. In cache locking mode, the lock enable bit (the LE bit) in CCR2 is set to 1. In non-cache-locking mode, the cache locking function is invalid.

When a cache miss occurs in cache locking mode by executing the prefetch instruction (PREF @Rn), the line of data pointed to by Rn is loaded into the cache according to bits 9 and 8 (the W3LOAD and W3LOCK bits) and bits 1 and 0 (the W2LOAD and W2LOCK bits) in CCR2. The relationship between the setting of each bit and a way, to be replaced when the prefetch instruction is executed, are listed in table 8.3. On the other hand, when the prefetch instruction is executed and a cache hit occurs, new data is not fetched and the entry which is already enabled is held. For example, when the prefetch instruction is executed with W3LOAD = 1 and W3LOCK = 1 specified in cache locking mode while one-line data already exists in way 0 which is specified by Rn, a cache hit occurs and data is not fetched to way 3.

In the cache access other than the prefetch instruction in cache locking mode, ways to be replaced by bits W3LOCK and W2LOCK are restricted. The relationship between the setting of each bit in CCR2 and ways to be replaced are listed in table 8.4.

Programs that change the contents of CCR2 should be placed in a cache-disabled space, and a cache-enabled space should be accessed after reading the contents of CCR2.

## 8.3 Operation

Operations for the operand cache are described here. Operations for the instruction cache are similar to those for the operand cache except for the address array not having the U bit, and there being no prefetch operation or write operation, or a write-back buffer.

### 8.3.1 Searching Cache

If the operand cache is enabled (OCE bit in CCR1 is 1), whenever data in a cache-enabled area is accessed, the cache will be searched to see if the desired data is in the cache. Figure 8.2 illustrates the method by which the cache is searched.

Entries are selected using bits 10 to 4 of the address used to access memory and the tag address of that entry is read. At this time, the upper three bits of the tag address are always cleared to 0. Bits 31 to 11 of the address used to access memory are compared with the read tag address. The address comparison uses all four ways. When the comparison shows a match and the selected entry is valid ( $V = 1$ ), a cache hit occurs. When the comparison does not show a match or the selected entry is not valid ( $V = 0$ ), a cache miss occurs. Figure 8.2 shows a hit on way 1.

Figure 8.2 Cache Search Scheme

### 8.3.2 Read Access

#### (1) Read Hit

In a read access, data is transferred from the cache to the CPU. LRU is updated so that the hit way is the latest.

#### (2) Read Miss

An external bus cycle starts and the entry is updated. The way replaced follows table 8.4. Entries are updated in 16-byte units. When the desired data that caused the miss is loaded from external memory to the cache, the data is transferred to the CPU in parallel with being loaded to the cache. When it is loaded in the cache, the V bit is set to 1, and LRU is updated so that the replaced way becomes the latest. In operand cache, the U bit is additionally cleared to 0. When the U bit of the entry to be replaced by updating the entry in write-back mode is 1, the cache update cycle starts after the entry is transferred to the write-back buffer. After the cache completes its update cycle, the write-back buffer writes the entry back to the memory. The write-back unit is 16 bytes. Cache updates and write-backs to memory are performed in wrap-around fashion. For example, if the value of the lower four bits of an address that triggers a read miss is H'4, the value of the lower four address bits changes from H'4 to H'8, H'C, and H'0, in that order, when cache updates or write-backs are performed.

### 8.3.3 Prefetch Operation (Only for Operand Cache)

#### (1) Prefetch Hit

LRU is updated so that the hit way becomes the latest. The contents in other caches are not modified. No data is transferred to the CPU.

#### (2) Prefetch Miss

No data is transferred to the CPU. The way to be replaced follows table 8.3. Other operations are the same in case of read miss.

8.3.4 Write Operation (Only for Operand Cache)

(1) Write Hit

In a write access in write-back mode, the data is written to the cache and no external memory write cycle is issued. The U bit of the entry written is set to 1 and LRU is updated so that the hit way becomes the latest.

In write-through mode, the data is written to the cache and an external memory write cycle is issued. The U bit of the written entry is not updated and LRU is updated so that the replaced way becomes the latest.

(2) Write Miss

In write-back mode, an external bus cycle starts when a write miss occurs, and the entry is updated. The way to be replaced follows table 8.4. When the U bit of the entry to be replaced is 1, the cache update cycle starts after the entry is transferred to the write-back buffer. Data is written to the cache, the U bit is set to 1, and the V bit is set to 1. LRU is updated so that the replaced way becomes the latest. After the cache completes its update cycle, the write-back buffer writes the entry back to the memory. The write-back unit is 16 bytes. Cache updates and write-backs to memory are performed in wrap-around fashion. For example, if the value of the lower four bits of an address that triggers a write miss is H'4, the value of the lower four address bits changes from H'4 to H'8, H'C, and H'0, in that order, when cache updates or write-backs are performed.

In write-through mode, no write to cache occurs in a write miss; the write is only to the external memory.

8.3.5 Write-Back Buffer (Only for Operand Cache)

When the U bit of the entry to be replaced in the write-back mode is 1, it must be written back to the external memory. To increase performance, the entry to be replaced is first transferred to the write-back buffer and fetching of new entries to the cache takes priority over writing back to the external memory. After the cache completes to fetch the new entry, the write-back buffer writes the entry back to external memory. During the write-back cycles, the cache can be accessed. The write-back buffer can hold one line of cache data (16 bytes) and its physical address. Figure 8.3 shows the configuration of the write-back buffer.

Figure 8.3 Write-Back Buffer Configuration

Operations in sections 8.3.2 to 8.3.5 are summarized in table 8.8.

**Table 8.8 Cache Operations**

[Legend]

x: Don't care.

Notes: Cache renewal cycle: 16-byte read access, write-back cycle in write-back buffer: 16-byte write access

\* Neither LRU renewed. LRU is renewed in all other cases.

### 8.3.6 Coherency of Cache and External Memory

Use software to ensure coherency between the cache and the external memory. When memory shared by this LSI and another device is mapped in the cache-enabled space, operate the memory-mapped cache to invalidate and write back as required.

## 8.4 Memory-Mapped Cache

To allow software management of the cache, cache contents can be read and written by means of MOV instructions. The instruction cache address array is mapped onto addresses H'F000 0000 to H'F07F FFFF, and the data array onto addresses H'F100 0000 to H'F17F FFFF. The operand cache address array is mapped onto addresses H'F080 0000 to H'F0FF FFFF, and the data array onto addresses H'F180 0000 to H'F1FF FFFF. Only longword can be used as the access size for the address array and data array, and instruction fetches cannot be performed.

### 8.4.1 Address Array

To access an address array, the 32-bit address field (for read/write accesses) and 32-bit data field (for write accesses) must be specified.

In the address field, specify the entry address selecting the entry, The W bit for selecting the way, and the A bit for specifying the existence of associative operation. In the W bit, B'00 is way 0, B'01 is way 1, B'10 is way 2, and B'11 is way 3. Since the access size of the address array is fixed at longword, specify B'00 for bits 1 and 0 of the address.

The tag address, LRU bits, U bit (only for operand cache), and V bit are specified as data. Always specify 0 for the upper three bits (bits 31 to 29) of the tag address.

For the address and data formats, see figure 8.4.

The following three operations are possible for the address array.

#### (1) Address Array Read

The tag address, LRU bits, U bit (only for operand cache), and V bit are read from the entry address specified by the address and the entry corresponding to the way. For the read operation, associative operation is not performed regardless of whether the associative bit (A bit) specified by the address is 1 or 0.

#### (2) Address-Array Write (Non-Associative Operation)

When the associative bit (A bit) in the address field is cleared to 0, write the tag address, LRU bits, U bit (only for operand cache), and V bit, specified by the data field, to the entry address specified by the address and the entry corresponding to the way. When writing to a cache line for which the U bit = 1 and the V bit = 1 in the operand cache address array, write the contents of the cache line back to memory, then write the tag address, LRU bits, U bit, and V bit specified by the data field. When 0 is written to the V bit, 0 must also be written to the U bit of that entry. When

memory write-backs are performed, the value of the lower four address bits changes from H'0 to H'4, H'8, and H'C, in that order.

### (3) Address-Array Write (Associative Operation)

When writing with the associative bit (A bit) of the address field set to 1, the addresses in the four ways for the entry specified by the address field are compared with the tag address that is specified by the data field. Write the U bit (only for operand cache) and the V bit specified by the data field to the entry of the way that has a hit. However, the tag address and LRU bits remain unchanged. When there is no way that has a hit, nothing is written and there is no operation.

This function is used to invalidate a specific entry in the cache. When the U bit of the entry that has had a hit is 1 in the operand cache, writing back should be performed. However, when 0 is written to the V bit, 0 must also be written to the U bit of that entry. When memory write-backs are performed, the value of the lower four address bits changes from H'0 to H'4, H'8, and H'C, in that order.

## 8.4.2 Data Array

To access a data array, the 32-bit address field (for read/write accesses) and 32-bit data field (for write accesses) must be specified. The address field specifies information for selecting the entry to be accessed; the data field specifies the longword data to be written to the data array.

Specify the entry address for selecting the entry, the L bit indicating the longword position within the (16-byte) line, and the W bit for selecting the way. In the L bit, B'00 is longword 0, B'01 is longword 1, B'10 is longword 2, and B'11 is longword 3. In the W bit, B'00 is way 0, B'01 is way 1, B'10 is way 2, and B'11 is way 3. Since the access size of the data array is fixed at longword, specify B'00 for bits 1 and 0 of the address.

For the address and data formats, see figure 8.4.

The following two operations are possible for the data array. Information in the address array is not modified by this operation.

### (1) Data Array Read

The data specified by the L bit in the address is read from the entry address specified by the address and the entry corresponding to the way.

## (2) Data Array Write

The longword data specified by the data is written to the position specified by the L bit in the address from the entry address specified by the address and the entry corresponding to the way.

**Figure 8.4 Specifying Address and Data for Memory-Mapped Cache Access**

### 8.4.3 Usage Examples

#### (1) Invalidating Specific Entries

Specific cache entries can be invalidated by writing 0 to the entry's V bit in the memory mapping cache access. When the A bit is 1, the tag address specified by the write data is compared to the tag address within the cache selected by the entry address, and data is written to the bits V and U specified by the write data when a match is found. If no match is found, there is no operation. When the V bit of an entry in the address array is set to 0, the entry is written back if the entry's U bit is 1.

An example when a write data is specified in R0 and an address is specified in R1 is shown below.

```
; R0=H'0110 0010; tag address(28-11)=B'0 0001 0001 0000 0000 0, U=0, V=0
; R1=H'F080 0088; operand cache address array access, entry=B'000 1000, A=1
;
MOV.L R0,@R1
```

#### (2) Reading the Data of a Specific Entry

The data section of a specific cache entry can be read by the memory mapping cache access. The longword indicated in the data field of the data array in figure 8.4 is read into the register.

An example when an address is specified in R0 and data is read in R1 is shown below.

```
; R0=H'F100 004C; instruction cache data array access, entry=B'000 0100,
; Way=0, longword address=3
;
MOV.L @R0,R1
```

#### 8.4.4 Notes

1. Programs that access memory-mapped cache of the operand cache should be placed in a cache-disabled space. Programs that access memory-mapped cache of the instruction cache should be placed in a cache-disabled space, and in each of the beginning and the end of that, two or more read accesses to on-chip peripheral modules or external address space (cache-disabled address) should be executed.
2. Rewriting the address array contents so that two or more ways are hit simultaneously is prohibited. Operation is not guaranteed if the address array contents are changed so that two or more ways are hit simultaneously.
3. Registers and memory-mapped cache can be accessed only by the CPU and not by the DMAC.

## Section 9 Bus State Controller (BSC)

The bus state controller (BSC) outputs control signals for various types of memory and external devices that are connected to the external address space. BSC functions enable this LSI to connect directly with SRAM, SDRAM, and other memory storage devices, and external devices.

### 9.1 Features

1. External address space
  - A maximum of 64 Mbytes for each of areas CS0 to CS7.
  - Can specify the normal space interface, SRAM interface with byte selection, burst ROM (clocked synchronous or asynchronous), MPX-I/O, burst MPX-I/O, SDRAM, and PCMCIA interface for each address space.
  - Can select the data bus width (8, 16, or 32 bits) for each address space.
  - Controls insertion of wait cycles for each address space.
  - Controls insertion of wait cycles for each read access and write access.
  - Can set independent idle cycles during the continuous access for five cases: read-write (in same space/different spaces), read-read (in same space/different spaces), the first cycle is a write access.
2. Normal space interface
  - Supports the interface that can directly connect to the SRAM.
3. Burst ROM interface (clocked asynchronous)
  - High-speed access to the ROM that has the page mode function.
4. MPX-I/O interface
  - Can directly connect to a peripheral LSI that needs an address/data multiplexing.
5. SDRAM interface
  - Can set the SDRAM in up to two areas.
  - Multiplex output for row address/column address.
  - Efficient access by single read/single write.
  - High-speed access in bank-active mode.
  - Supports an auto-refresh and self-refresh.
  - Supports low-frequency and power-down modes.
  - Issues MRS and EMRS commands.

6. PCMCIA direct interface
  - Supports the IC memory card and I/O card interface defined in JEIDA specifications Ver. 4.2 (PCMCIA2.1 Rev. 2.1).
  - Wait-cycle insertion controllable by program.
7. SRAM interface with byte selection
  - Can connect directly to a SRAM with byte selection.
8. Burst MPX-I/O interface
  - Can connect directly to a peripheral LSI that needs an address/data multiplexing.
  - Supports burst transfer.
9. Burst ROM interface (clocked synchronous)
  - Can connect directly to a ROM of the clocked synchronous type.
10. Bus arbitration
  - Shares all of the resources with other CPU and outputs the bus enable after receiving the bus request from external devices.
11. Refresh function
  - Supports the auto-refresh and self-refresh functions.
  - Specifies the refresh interval using the refresh counter and clock selection.
  - Can execute concentrated refresh by specifying the refresh counts (1, 2, 4, 6, or 8).
12. Usage as interval timer for refresh counter
  - Generates an interrupt request at compare match.

Figure 9.1 shows a block diagram of the BSC.

**Figure 9.1 Block Diagram of BSC**

## 9.2 Input/Output Pins

Table 9.1 shows the pin configuration of the BSC.

**Table 9.1 Pin Configuration**

| Name                                                    | I/O    | Function                                                                                                                                                                                                                                                                                                                                                               |

## 9.3 Area Overview

### 9.3.1 Address Map

In the architecture, this LSI has a 32-bit address space, which is divided into cache-enabled, cache-disabled, and on-chip spaces (on-chip RAM, on-chip peripheral modules, and reserved areas) according to the upper bits of the address.

External address spaces CS0 to CS7 are cache-enabled when internal address A29 = 0 or cache-disabled when A29 = 1.

The kind of memory to be connected and the data bus width are specified in each partial space. The address map for the external address space is listed below.

**Table 9.2 Address Map**

| Internal Address         | Space | Memory to be Connected                                           | Cache          |
|--------------------------|-------|------------------------------------------------------------------|----------------|
| H'00000000 to H'03FFFFFF | CS0   | Normal space, burst ROM (asynchronous or synchronous)            | Cache-enabled  |
| H'04000000 to H'07FFFFFF | CS1   | Normal space, SRAM with byte selection                           |                |
| H'08000000 to H'0BFFFFFF | CS2   | Normal space, SRAM with byte selection, SDRAM                    |                |
| H'0C000000 to H'0FFFFFFF | CS3   | Normal space, SRAM with byte selection, SDRAM                    |                |
| H'10000000 to H'13FFFFFF | CS4   | Normal space, SRAM with byte selection, burst ROM (asynchronous) |                |
| H'14000000 to H'17FFFFFF | CS5   | Normal space, SRAM with byte selection, MPX-I/O, PCMCIA          |                |
| H'18000000 to H'1BFFFFFF | CS6   | Normal space, SRAM with byte selection, burst MPX-I/O, PCMCIA    |                |
| H'1C000000 to H'1FFFFFFF | CS7   | Normal space, SRAM with byte selection                           |                |
| H'20000000 to H'23FFFFFF | CS0   | Normal space, burst ROM (asynchronous or synchronous)            | Cache-disabled |
| H'24000000 to H'27FFFFFF | CS1   | Normal space, SRAM with byte selection                           |                |
| H'28000000 to H'2BFFFFFF | CS2   | Normal space, SRAM with byte selection, SDRAM                    |                |
| H'2C000000 to H'2FFFFFFF | CS3   | Normal space, SRAM with byte selection, SDRAM                    |                |
| H'30000000 to H'33FFFFFF | CS4   | Normal space, SRAM with byte selection, burst ROM (asynchronous) |                |
| H'34000000 to H'37FFFFFF | CS5   | Normal space, SRAM with byte selection, MPX-I/O, PCMCIA          |                |
| H'38000000 to H'3BFFFFFF | CS6   | Normal space, SRAM with byte selection, burst MPX-I/O, PCMCIA    |                |
| H'3C000000 to H'3FFFFFFF | CS7   | Normal space, SRAM with byte selection                           |                |

| Internal Address         | Space | Memory to be Connected                     | Cache |
|--------------------------|-------|--------------------------------------------|-------|
| H'40000000 to H'FFFBFFFF | Other | On-chip RAM, reserved area*                | —     |
| H'FFFC0000 to H'FFFFFFF  | Other | On-chip peripheral modules, reserved area* | —     |

Note: \* For the on-chip RAM space, access the addresses shown in section 27, On-Chip RAM. For the on-chip peripheral module space, access the addresses shown in section 30, List of Registers. Do not access addresses which are not described in these sections. Otherwise, the correct operation cannot be guaranteed.

### 9.3.2 Data Bus Width and Related Pin Settings for Each Area

The data bus width of area 0 can be set to either 16 or 32 bits by means of an external pin, but it cannot be changed by a program after startup. The initial data bus width of areas 1 to 7 is the same as that of area 0, but it can be changed by a program by means of register settings.

Immediately after a power-on reset, certain address and data bus settings, and functions of  $\overline{\text{CS0}}$  and  $\overline{\text{RD}}$ , are automatically selected as initial functions required to read the area 0 ROM. The other pins are set as general ports as the initial function setting, and they cannot be used until their functions are set by a program. Do not perform other than read access to area 0 until the pin function settings have been completed.

Table 9.3 lists the external pin settings and the initial state of each area.

Note that sample access waveforms are shown in this section for pins such as  $\overline{\text{BS}}$ ,  $\overline{\text{RD}}/\overline{\text{WR}}$ , and  $\overline{\text{WEn}}$ , and these functions are available after they are selected through the pin function controller. For example, after startup with the 32-bit bus width, changing the bus width of the areas other than area 0 to 16 bits requires setting the function of the A1 pin, and changing the bus width to 8 bits requires setting the functions of the A1 and A0 pins.

For details on pin function settings, see section 25, Pin Function Controller (PFC).

**Table 9.3 External Pin Setting (MD) and Initial State Of Each Area**

| MD | Item                     | Area 0                                                                                                                                                   | Areas 1 to 7                                               |
|----|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| 1  | Data bus width           | Bus width fixed at 32 bits.<br>Cannot be changed.                                                                                                        | Initial bus width 32 bits.<br>Can be changed by a program. |
|    | BSC-related pin settings | Only A20 to A2, D31 to D0, $\overline{CS0}$ , and $\overline{RD}$ pin functions are set automatically. The other pin functions must be set by a program. |                                                            |
| 0  | Data bus width           | Bus width fixed at 16 bits.<br>Cannot be changed.                                                                                                        | Initial bus width 16 bits.<br>Can be changed by a program. |
|    | BSC-related pin settings | Only A20 to A1, D15 to D0, $\overline{CS0}$ , and $\overline{RD}$ pin functions are set automatically. The other pin functions must be set by a program. |                                                            |

Notes: 1. In area 0, when connecting ROM that uses address lines A21 and above, pull-down processing of address lines A21 and above must be performed on the board.

2. There may be limitations on the available data bus widths depending on the type of memory used. For details, see 9.4.2, CSn Space Bus Control Register.

3. It is not possible to use area 7 and connect a device with an 8-bit bus width at the same time because the  $\overline{CS7}$  and A0 functions are assigned to the same pin.

## 9.4 Register Descriptions

The BSC has the following registers.

Do not access spaces other than area 0 until settings of the connected memory interface are completed.

**Table 9.4 Register Configuration**

| Register Name                         | Abbreviation | R/W | Initial Value | Address    | Access Size |
|---------------------------------------|--------------|-----|---------------|------------|-------------|
| Common control register               | CMNCR        | R/W | H'00001010    | H'FFFC0000 | 32          |
| CS0 space bus control register        | CS0BCR       | R/W | H'36DB0600*   | H'FFFC0004 | 32          |
| CS1 space bus control register        | CS1BCR       | R/W | H'36DB0600*   | H'FFFC0008 | 32          |
| CS2 space bus control register        | CS2BCR       | R/W | H'36DB0600*   | H'FFFC000C | 32          |
| CS3 space bus control register        | CS3BCR       | R/W | H'36DB0600*   | H'FFFC0010 | 32          |
| CS4 space bus control register        | CS4BCR       | R/W | H'36DB0600*   | H'FFFC0014 | 32          |
| CS5 space bus control register        | CS5BCR       | R/W | H'36DB0600*   | H'FFFC0018 | 32          |
| CS6 space bus control register        | CS6BCR       | R/W | H'36DB0600*   | H'FFFC001C | 32          |
| CS7 space bus control register        | CS7BCR       | R/W | H'36DB0600*   | H'FFFC0020 | 32          |
| CS0 space wait control register       | CS0WCR       | R/W | H'00000500    | H'FFFC0028 | 32          |
| CS1 space wait control register       | CS1WCR       | R/W | H'00000500    | H'FFFC002C | 32          |
| CS2 space wait control register       | CS2WCR       | R/W | H'00000500    | H'FFFC0030 | 32          |
| CS3 space wait control register       | CS3WCR       | R/W | H'00000500    | H'FFFC0034 | 32          |
| CS4 space wait control register       | CS4WCR       | R/W | H'00000500    | H'FFFC0038 | 32          |
| CS5 space wait control register       | CS5WCR       | R/W | H'00000500    | H'FFFC003C | 32          |
| CS6 space wait control register       | CS6WCR       | R/W | H'00000500    | H'FFFC0040 | 32          |
| CS7 space wait control register       | CS7WCR       | R/W | H'00000500    | H'FFFC0044 | 32          |
| SDRAM control register                | SDCR         | R/W | H'00000000    | H'FFFC004C | 32          |
| Refresh timer control/status register | RTCSR        | R/W | H'00000000    | H'FFFC0050 | 32          |
| Refresh timer counter                 | RTCNT        | R/W | H'00000000    | H'FFFC0054 | 32          |
| Refresh time constant register        | RTCOR        | R/W | H'00000000    | H'FFFC0058 | 32          |

Note: \* This is an initial value when this LSI is started by the external pin (MD) with the bus width set to 32 bits. The initial value will be H'36DB0400 when the bus width is set to 16 bits.

### 9.4.1 Common Control Register (CMNCR)

CMNCR is a 32-bit register that controls the common items for each area.

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit:           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|                | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| R/W:           | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  |

Note: \* For Hi-Z control of CKIO, see section 4, Clock Pulse Generator (CPG).

### 9.4.2 CSn Space Bus Control Register (CSnBCR) (n = 0 to 7)

CSnBCR is a 32-bit readable/writable register that specifies the function of each area, the number of idle cycles between bus cycles, and the bus width.

Do not access external memory other than area 0 until CSnBCR initial setting is completed.

Idle cycles may be inserted even when they are not specified. For details, see section 9.5.12, Wait between Access Cycles.

Note: \* CSnBCR samples the external pins (MD) that specify the bus width at power-on reset.

### 9.4.3 CSn Space Wait Control Register (CSnWCR) (n = 0 to 7)

CSnWCR specifies various wait cycles for memory access. The bit configuration of this register varies as shown below according to the memory type (TYPE2 to TYPE0) specified by the CSn space bus control register (CSnBCR). Specify CSnWCR before accessing the target area. Specify CSnBCR first, then specify CSnWCR.

#### (1) Normal Space, SRAM with Byte Selection, MPX-I/O

- CS0WCR

### 9.4.4 SDRAM Control Register (SDCR)

SDCR specifies the method to refresh and access SDRAM, and the types of SDRAMs to be connected.

### 9.4.5 Refresh Timer Control/Status Register (RTCSR)

RTCSR specifies various items about refresh for SDRAM.

When RTCSR is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

The phase of the clock for incrementing the count in the refresh timer counter (RTCNT) is adjusted only by a power-on reset. Note that there is an error in the time until the compare match flag is set for the first time after the timer is started with the CKS[2:0] bits being set to a value other than B'000.

### 9.4.6 Refresh Timer Counter (RTCNT)

RTCNT is an 8-bit counter that increments using the clock selected by bits CKS[2:0] in RTCSR. When RTCNT matches RTCOR, RTCNT is cleared to 0. The value in RTCNT returns to 0 after counting up to 255. When the RTCNT is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

9.4.7 Refresh Time Constant Register (RTCOR)

RTCOR is an 8-bit register. When RTCOR matches RTCNT, the CMF bit in RTCSR is set to 1 and RTCNT is cleared to 0.

When the RFSH bit in SDCR is 1, a memory refresh request is issued by this matching signal. This request is maintained until the refresh operation is performed. If the request is not processed when the next matching occurs, the previous request is ignored.

The  $\overline{\text{REFOUT}}$  signal can be asserted when a refresh request is generated while the bus is released. For details, see the description of Relationship between Refresh Requests and Bus Cycles in section 9.5.6 (9), Relationship between Refresh Requests and Bus Cycles, and section 9.5.13, Bus Arbitration.

When the CMIE bit in RTCSR is set to 1, an interrupt request is issued by this matching signal. The request continues to be output until the CMF bit in RTCSR is cleared. Clearing the CMF bit only affects the interrupt request and does not clear the refresh request. Therefore, a combination of refresh request and interval timer interrupt can be specified so that the number of refresh requests are counted by using timer interrupts while refresh is performed periodically.

When RTCOR is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

## 9.5 Operation

### 9.5.1 Endian/Access Size and Data Alignment

This LSI supports both big endian, in which the most significant byte (MSB) of data is that in the direction of the 0th address, and little endian, in which the least significant byte (LSB) is that in the direction of the 0th address. In the initial state after a power-on reset, all areas will be in big endian mode. Little endian cannot be selected for area 0. However, the endian of areas 1 to 7 can be changed by the setting in the CSnBCR register setting as long as the target space is not being accessed.

Three data bus widths (8 bits, 16 bits, and 32 bits) are selectable for areas 1 to 7, allowing the connection of normal memory and of SRAM with byte selection. Two data bus widths (16 bits and 32 bits) are available for SDRAM. Two data bus widths (8 bits and 16 bits) are available for the PCMCIA interface. For MPX-I/O, the data bus width can be fixed to either 8 or 16 bits, or made selectable as 8 bits or 16 bits by one of the address lines. The data bus width for burst MPX-I/O is fixed at 32 bits. Data alignment is in accord with the data bus width selected for the device. This also means that four read operations are required to read longword data from a byte-width device. In this LSI, data alignment and conversion of data length is performed automatically between the respective interfaces. The data bus width of area 0 is fixed to 16 bits or 32 bits by the MD pin setting at a power-on reset.

Tables 9.5 to 9.10 show the relationship between device data width and access unit. Note that the correspondence between addresses and strobe signals for the 32- and 16-bit bus widths depends on the endian setting. For example, with big endian and a 32-bit bus width,  $\overline{\text{WE3}}$  corresponds to the 0th address, which is represented by  $\overline{\text{WE0}}$  when little endian has been selected. Area 0 cannot be set to little endian mode. In addition, fetching instructions from a little endian area can be difficult because 32-bit and 16-bit accesses are mixed, so big endian mode should be used for instruction execution.

## 9.5.2 Normal Space Interface

### (1) Basic Timing

For access to a normal space, this LSI uses strobe signal output in consideration of the fact that mainly static RAM will be directly connected. When using SRAM with a byte-selection pin, see section 9.5.8, SRAM Interface with Byte Selection. Figure 9.2 shows the basic timings of normal space access. A no-wait normal access is completed in two cycles. The  $\overline{BS}$  signal is asserted for one cycle to indicate the start of a bus cycle.

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.2 Normal Space Basic Access Timing (Access Wait 0)**

There is no access size specification when reading. The correct access start address is output in the least significant bit of the address, but since there is no access size specification, 32 bits are always

read in case of a 32-bit device, and 16 bits in case of a 16-bit device. When writing, only the  $\overline{WEn}$  signal for the byte to be written is asserted.

It is necessary to output the data that has been read using  $\overline{RD}$  when a buffer is established in the data bus. The  $\overline{RD}/\overline{WR}$  signal is in a read state (high output) when no access has been carried out. Therefore, care must be taken when controlling the external data buffer, to avoid collision.

Figures 9.3 and 9.4 show the basic timings of normal space access. If the WM bit in CSnWCR is cleared to 0, a Tnop cycle is inserted after the CSn space access to evaluate the external wait (figure 9.3). If the WM bit in CSnWCR is set to 1, external waits are ignored and no Tnop cycle is inserted (figure 9.4).

**Figure 9.3 Continuous Access for Normal Space 1**  
**Bus Width = 16 Bits, Longword Access, CSnWCR.WM Bit = 0**  
**(Access Wait = 0, Cycle Wait = 0)**

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.4 Continuous Access for Normal Space 2**  
**Bus Width = 16 Bits, Longword Access, CSnWCR.WM Bit = 1**  
**(Access Wait = 0, Cycle Wait = 0)**

**Figure 9.5 Example of 32-Bit Data-Width SRAM Connection**

**Figure 9.6 Example of 16-Bit Data-Width SRAM Connection**

**Figure 9.7 Example of 8-Bit Data-Width SRAM Connection**

### 9.5.3 Access Wait Control

Wait cycle insertion on a normal space access can be controlled by the settings of bits WR3 to WR0 in CSnWCR. It is possible for areas 1, 4, 5, and 7 to insert wait cycles independently in read access and in write access. Areas 0, 2, 3, and 6 have common access wait for read cycle and write cycle. The specified number of  $T_w$  cycles are inserted as wait cycles in a normal space access shown in figure 9.8.

**Figure 9.8 Wait Timing for Normal Space Access (Software Wait Only)**

When the WM bit in CSnWCR is cleared to 0, the external wait input  $\overline{\text{WAIT}}$  signal is also sampled.  $\overline{\text{WAIT}}$  pin sampling is shown in figure 9.9. A 2-cycle wait is specified as a software wait. The  $\overline{\text{WAIT}}$  signal is sampled on the falling edge of CKIO at the transition from the T1 or Tw cycle to the T2 cycle.

**Figure 9.9 Wait Cycle Timing for Normal Space Access  
(Wait Cycle Insertion Using  $\overline{\text{WAIT}}$  Signal)**

### 9.5.4 $\overline{CSn}$ Assert Period Expansion

The number of cycles from  $\overline{CSn}$  assertion to  $\overline{RD}$ ,  $\overline{WEn}$  assertion can be specified by setting bits SW1 and SW0 in CSnWCR. The number of cycles from  $\overline{RD}$ ,  $\overline{WEn}$  negation to  $\overline{CSn}$  negation can be specified by setting bits HW1 and HW0. Therefore, a flexible interface to an external device can be obtained. Figure 9.10 shows an example. A  $T_h$  cycle and a  $T_f$  cycle are added before and after an ordinary cycle, respectively. In these cycles,  $\overline{RD}$  and  $\overline{WEn}$  are not asserted, while other signals are asserted. The data output is prolonged to the  $T_f$  cycle, and this prolongation is useful for devices with slow writing operations.

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.10  $\overline{CSn}$  Assert Period Expansion**

### 9.5.5 MPX-I/O Interface

Access timing for the MPX space is shown below. In the MPX space,  $\overline{CS5}$ ,  $\overline{AH}$ ,  $\overline{RD}$ , and  $\overline{WEn}$  signals control the accessing. The basic access for the MPX space consists of 2 cycles of address output followed by an access to a normal space. The bus width for the address output cycle or the data input/output cycle is fixed to 8 bits or 16 bits. Alternatively, it can be 8 bits or 16 bits depending on the address to be accessed.

Output of the addresses D15 to D0 or D7 to D0 is performed from cycle Ta2 to cycle Ta3. Because cycle Ta1 has a high-impedance state, collisions of addresses and data can be avoided without inserting idle cycles, even in continuous access cycles. Address output is increased to 3 cycles by setting the MPXW bit in CS5WCR to 1.

The  $\overline{RD}/\overline{WR}$  signal is output at the same time as the  $\overline{CS5}$  signal; it is high in the read cycle and low in the write cycle.

The data cycle is the same as that in a normal space access.

The delay cycles specified by SW[1:0] are inserted between the Ta3 and T1 cycles. The delay cycles specified by HW[1:0] are added after the T2 cycle.

Timing charts are shown in figures 9.11 to 9.13.

Note: \* The waveform for DACKn is when active low is specified.

## 9.5.6 SDRAM Interface

### (1) SDRAM Direct Connection

The SDRAM that can be connected to this LSI is a product that has 11/12/13 bits of row address, 8/9/10 bits of column address, 4 or less banks, and uses the A10 pin for setting precharge mode in read and write command cycles.

The control signals for direct connection of SDRAM are  $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASU}}$ ,  $\overline{\text{CASL}}$ ,  $\text{RD}/\overline{\text{WR}}$ ,  $\text{DQM}_{\text{UU}}$ ,  $\text{DQM}_{\text{UL}}$ ,  $\text{DQMLU}$ ,  $\text{DQMLL}$ ,  $\text{CKE}$ ,  $\overline{\text{CS2}}$ , and  $\overline{\text{CS3}}$ . All the signals other than  $\overline{\text{CS2}}$  and  $\overline{\text{CS3}}$  are common to all areas, and signals other than  $\text{CKE}$  are valid when  $\overline{\text{CS2}}$  or  $\overline{\text{CS3}}$  is asserted. SDRAM can be connected to up to 2 spaces. The data bus width of the area that is connected to SDRAM can be set to 32 or 16 bits.

Burst read/single write (burst length 1) and burst read/burst write (burst length 1) are supported as the SDRAM operating mode.

Commands for SDRAM can be specified by  $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASU}}$ ,  $\overline{\text{CASL}}$ ,  $\text{RD}/\overline{\text{WR}}$ , and specific address signals. These commands supports:

- NOP
- Auto-refresh (REF)
- Self-refresh (SELF)
- All banks pre-charge (PALL)
- Specified bank pre-charge (PRE)
- Bank active (ACTV)
- Read (READ)
- Read with pre-charge (READA)
- Write (WRIT)
- Write with pre-charge (WRITA)
- Write mode register (MRS, EMRS)

The byte to be accessed is specified by  $\text{DQM}_{\text{UU}}$ ,  $\text{DQM}_{\text{UL}}$ ,  $\text{DQMLU}$ , and  $\text{DQMLL}$ . Reading or writing is performed for a byte whose corresponding  $\text{DQM}_{\text{xx}}$  is low. For details on the relationship between  $\text{DQM}_{\text{xx}}$  and the byte to be accessed, see section 9.5.1, Endian/Access Size and Data Alignment.

Figures 9.14 to 9.16 show examples of the connection of the SDRAM with the LSI.

As shown in figure 9.16, two sets of SDRAMs of 32 Mbytes or smaller can be connected to the same CS space by using  $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASU}}$ , and  $\overline{\text{CASL}}$ . In this case, a total of 8 banks are assigned to the same CS space: 4 banks specified by  $\overline{\text{RASL}}$  and  $\overline{\text{CASL}}$ , and 4 banks specified by  $\overline{\text{RASU}}$  and  $\overline{\text{CASU}}$ . When accessing the address with  $\text{A25} = 0$ ,  $\overline{\text{RASL}}$  and  $\overline{\text{CASL}}$  are asserted. When accessing the address with  $\text{A25} = 1$ ,  $\overline{\text{RASU}}$  and  $\overline{\text{CASU}}$  are asserted.

**Figure 9.14 Example of 32-Bit Data Width SDRAM Connection**  
( $\overline{\text{RASU}}$  and  $\overline{\text{CASU}}$  are Not Used)

**Figure 9.15 Example of 16-Bit Data Width SDRAM Connection**  
**( $\overline{RAS}_U$  and  $\overline{CAS}_U$  are Not Used)**

**Figure 9.16 Example of 16-Bit Data Width SDRAM Connection  
( $\overline{\text{RASU}}$  and  $\overline{\text{CASU}}$  are Used)**

## (2) Address Multiplexing

An address multiplexing is specified so that SDRAM can be connected without external multiplexing circuitry according to the setting of bits BSZ[1:0] in CSnBCR, bits A2ROW[1:0], and A2COL[1:0], A3ROW[1:0], and A3COL[1:0] in SDCR. Tables 9.11 to 9.16 show the relationship between the settings of bits BSZ[1:0], A2ROW[1:0], A2COL[1:0], A3ROW[1:0], and A3COL[1:0] and the bits output at the address pins. Do not specify those bits in the manner other than this table, otherwise the operation of this LSI is not guaranteed. A25 to A18 are not multiplexed and the original values of address are always output at these pins.

When the data bus width is 16 bits (BSZ1 and BSZ0 = B'10), A0 of SDRAM specifies a word address. Therefore, connect this A0 pin of SDRAM to the A1 pin of the LSI; the A1 pin of SDRAM to the A2 pin of the LSI, and so on. When the data bus width is 32 bits (BSZ1 and BSZ0 = B'11), the A0 pin of SDRAM specifies a longword address. Therefore, connect this A0 pin of SDRAM to the A2 pin of the LSI; the A1 pin of SDRAM to the A3 pin of the LSI, and so on.

**Table 9.11 Relationship between BSZ[1:0], A2/3ROW[1:0], A2/3COL[1:0], and Address Multiplex Output (1)-1**

| Setting                                                                    |                             |                                |           |                                |        |

Example of connected memory

512-Mbit product (8 Mwords × 16 bits × 4 banks, column 10 bits product): 1

Notes: 1. L/H is a bit used in the command specification; it is fixed at low or high according to the access mode.

2. Bank address specification

3. Only the  $\overline{\text{RASL}}$  pin is asserted because the A25 pin specified the bank address.  $\overline{\text{RASU}}$  is not asserted.

### (3) Burst Read

A burst read occurs in the following cases with this LSI.

- Access size in reading is larger than data bus width.
- 16-byte transfer in cache miss.
- 16-byte transfer by DMAC
- 16-byte to 128-byte transfer by LCDC

This LSI always accesses the SDRAM with burst length 1. For example, read access of burst length 1 is performed consecutively 4 times to read 16-byte continuous data from the SDRAM that is connected to a 32-bit data bus. This access is called the burst read with the burst number 4. Table 9.17 shows the relationship between the access size and the number of bursts.

Note: For details, see section 24, LCD Controller (LCDC).

**Table 9.17 Relationship between Access Size and Number of Bursts**

| Bus Width | Access Size | Number of Bursts |
|-----------|-------------|------------------|
| 16 bits   | 8 bits      | 1                |
|           | 16 bits     | 1                |
|           | 32 bits     | 2                |
|           | 16 bytes    | 8                |
|           | 32 bytes*   | 16               |
|           | 64 bytes*   | 32               |
|           | 128 bytes*  | 64               |
| 32 bits   | 8 bits      | 1                |
|           | 16 bits     | 1                |
|           | 32 bits     | 1                |
|           | 16 bytes    | 4                |
|           | 32 bytes*   | 8                |
|           | 64 bytes*   | 16               |
|           | 128 bytes*  | 32               |

Note: \* 32-, 64-, or 128-byte access occurs when the LCDC is used. For details, see section 24, LCD Controller (LCDC).

Figures 9.17 and 9.18 show a timing chart in burst read. In burst read, an ACTV command is output in the Tr cycle, the READ command is issued in the Tc1, Tc2, and Tc3 cycles, the READA command is issued in the Tc4 cycle, and the read data is received at the rising edge of the external clock (CKIO) in the Td1 to Td4 cycles. The Tap cycle is used to wait for the completion of an auto-precharge induced by the READA command in the SDRAM. In the Tap cycle, a new command will not be issued to the same bank. However, access to another CS space or another bank in the same SDRAM space is enabled. The number of Tap cycles is specified by the WTRP1 and WTRP0 bits in CS3WCR.

In this LSI, wait cycles can be inserted by specifying each bit in CS3WCR to connect the SDRAM in variable frequencies. Figure 9.18 shows an example in which wait cycles are inserted. The number of cycles from the Tr cycle where the ACTV command is output to the Tc1 cycle where the READ command is output can be specified using the WTRCD1 and WTRCD0 bits in CS3WCR. If the WTRCD1 and WTRCD0 bits specify one cycles or more, a Trw cycle where the NOT command is issued is inserted between the Tr cycle and Tc1 cycle. The number of cycles from the Tc1 cycle where the READ command is output to the Td1 cycle where the read data is latched can be specified for the CS2 and CS3 spaces independently, using the A2CL1 and A2CL0 bits in CS2WCR or the A3CL1 and A3CL0 bits in CS3WCR and WTRCD0 bit in CS3WCR. The number of cycles from Tc1 to Td1 corresponds to the SDRAM CAS latency. The CAS latency for the SDRAM is normally defined as up to three cycles. However, the CAS latency in this LSI can be specified as 1 to 4 cycles. This CAS latency can be achieved by connecting a latch circuit between this LSI and the SDRAM.

A Tde cycle is an idle cycle required to transfer the read data into this LSI and occurs once for every burst read or every single read.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
 2. The waveform for DACKn is when active low is specified.

**Figure 9.17 Burst Read Basic Timing (CAS Latency 1, Auto Pre-Charge)**

**Figure 9.18 Burst Read Wait Specification Timing (CAS Latency 2, WTRCD[1:0] = 1 Cycle, Auto Pre-Charge)**

#### (4) Single Read

A read access ends in one cycle when data exists in a cache-disabled space and the data bus width is larger than or equal to the access size. As the SDRAM is set to the burst read with the burst length 1, only the required data is output. A read access that ends in one cycle is called single read.

Figure 9.19 shows the single read basic timing.

**Figure 9.19 Basic Timing for Single Read (CAS Latency 1, Auto Pre-Charge)**

## (5) Burst Write

A burst write occurs in the following cases in this LSI.

- Access size in writing is larger than data bus width.
- Write-back of the cache
- 16-byte transfer in DMAC

This LSI always accesses SDRAM with burst length 1. For example, write access of burst length 1 is performed continuously 4 times to write 16-byte continuous data to the SDRAM that is connected to a 32-bit data bus. This access is called burst write with the burst number 4. The relationship between the access size and the number of bursts is shown in table 9.17. Figure 9.20 shows a timing chart for burst writes. In burst write, an ACTV command is output in the Tr cycle, the WRIT command is issued in the Tc1, Tc2, and Tc3 cycles, and the WRITA command is issued to execute an auto-precharge in the Tc4 cycle. In the write cycle, the write data is output simultaneously with the write command. After the write command with the auto-precharge is output, the Trw1 cycle that waits for the auto-precharge initiation is followed by the Tap cycle that waits for completion of the auto-precharge induced by the WRITA command in the SDRAM. Between the Trw1 and the Tap cycle, a new command will not be issued to the same bank. However, access to another CS space or another bank in the same SDRAM space is enabled. The number of Trw1 cycles is specified by the TRWL1 and TRWL0 bits in CS3WCR. The number of Tap cycles is specified by the WTRP1 and WTRP0 bits in CS3WCR.

- Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
 2. The waveform for  $\overline{DACK}_n$  is when active low is specified.

**Figure 9.20 Basic Timing for Burst Write (Auto Pre-Charge)**

## (6) Single Write

A write access ends in one cycle when data is written in a cache-disabled space and the data bus width is larger than or equal to access size. As a single write or burst write with burst length 1 is set in SDRAM, only the required data is output. The write access that ends in one cycle is called single write. Figure 9.21 shows the single write basic timing.

- Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
2. The waveform for DACKn is when active low is specified.

**Figure 9.21 Single Write Basic Timing (Auto-Precharge)**

## (7) Bank Active

The SDRAM bank function can be used to support high-speed access to the same row address. When the BACTV bit in SDCR is 1, access is performed using commands without auto-precharge (READ or WRIT). This function is called bank-active function. This function is valid only for either the upper or lower bits of area 3. When area 3 is set to bank-active mode, area 2 should be set to normal space or SRAM with byte selection. When areas 2 and 3 are both set to SDRAM or both the upper and lower bits of area 3 are connected to SDRAM, auto precharge mode must be set.

When the bank-active function is used, precharging is not performed when the access ends. When accessing the same row address in the same bank, it is possible to issue the READ or WRIT command immediately, without issuing an ACTV command. As SDRAM is internally divided into several banks, it is possible to activate one row address in each bank. If the next access is to a different row address, a PRE command is first issued to precharge the relevant bank, then when precharging is completed, the access is performed by issuing an ACTV command followed by a READ or WRIT command. If this is followed by an access to a different row address, the access time will be longer because of the precharging performed after the access request is issued. The number of cycles between issuance of the PRE command and the ACTV command is determined by the WTRP1 and WTPR0 bits in CS3WCR.

In a write, when an auto-precharge is performed, a command cannot be issued to the same bank for a period of  $Trwl + Tap$  cycles after issuance of the WRITA command. When bank active mode is used, READ or WRIT commands can be issued successively if the row address is the same. The number of cycles can thus be reduced by  $Trwl + Tap$  cycles for each write.

There is a limit on tRAS, the time for placing each bank in the active state. If there is no guarantee that there will not be a cache hit and another row address will be accessed within the period in which this value is maintained by program execution, it is necessary to set auto-refresh and set the refresh cycle to no more than the maximum value of tRAS.

A burst read cycle without auto-precharge is shown in figure 9.22, a burst read cycle for the same row address in figure 9.23, and a burst read cycle for different row addresses in figure 9.24. Similarly, a burst write cycle without auto-precharge is shown in figure 9.25, a burst write cycle for the same row address in figure 9.26, and a burst write cycle for different row addresses in figure 9.27.

In figure 9.23, a Tnop cycle in which no operation is performed is inserted before the Tc cycle that issues the READ command. The Tnop cycle is inserted to acquire two cycles of CAS latency for the DQMxx signal that specifies the read byte in the data read from the SDRAM. If the CAS

latency is specified as two cycles or more, the T<sub>nop</sub> cycle is not inserted because the two cycles of latency can be acquired even if the DQM<sub>xx</sub> signal is asserted after the T<sub>c</sub> cycle.

When bank active mode is set, if only access cycles to the respective banks in the area 3 space are considered, as long as access cycles to the same row address continue, the operation starts with the cycle in figure 9.22 or 9.25, followed by repetition of the cycle in figure 9.23 or 9.26. An access to a different area during this time has no effect. If there is an access to a different row address in the bank active state, the bus cycle in figure 9.24 or 9.27 is executed instead of that in figure 9.23 or 9.26. In bank active mode, too, all banks become inactive after a refresh cycle or after the bus is released as the result of bus arbitration.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.

2. The waveform for DACK<sub>n</sub> is when active low is specified.

## (8) Refreshing

This LSI has a function for controlling SDRAM refreshing. Auto-refreshing can be performed by clearing the RMODE bit to 0 and setting the RFSH bit to 1 in SDCR. A continuous refreshing can be performed by setting the RRC2 to RRC0 bits in RTCSR. If SDRAM is not accessed for a long period, self-refresh mode, in which the power consumption for data retention is low, can be activated by setting both the RMODE bit and the RFSH bit to 1.

### (a) Auto-refreshing

Refreshing is performed at intervals determined by the input clock selected by bits CKS2 to CKS0 in RTCSR, and the value set by in RTCOR. The value of bits CKS2 to CKS0 in RTCOR should be set so as to satisfy the refresh interval stipulation for the SDRAM used. First make the settings for RTCOR, RTCNT, and the RMODE and RFSH bits in SDCR, then make the CKS2 to CKS0 and RRC2 to RRC0 settings. When the clock is selected by bits CKS2 to CKS0, RTCNT starts counting up from the value at that time. The RTCNT value is constantly compared with the RTCOR value, and if the two values are the same, a refresh request is generated and an auto-refresh is performed for the number of times specified by the RRC2 to RRC0. At the same time, RTCNT is cleared to zero and the count-up is restarted.

Figure 9.28 shows the auto-refresh cycle timing. After starting, the auto refreshing, PALL command is issued in the  $T_p$  cycle to make all the banks to pre-charged state from active state when some bank is being pre-charged. Then REF command is issued in the  $T_{rr}$  cycle after inserting idle cycles of which number is specified by the WTRP1 and WTRP0 bits in CS3WCR. A new command is not issued for the duration of the number of cycles specified by the WTRC1 and WTRC0 bits in CS3WCR after the  $T_{rr}$  cycle. The WTRC1 and WTRC0 bits must be set so as to satisfy the SDRAM refreshing cycle time stipulation ( $t_{RC}$ ). An idle cycle is inserted between the  $T_p$  cycle and  $T_{rr}$  cycle when the setting value of the WTRP1 and WTRP0 bits in CS3WCR is longer than or equal to 1 cycle.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
 2. The waveform for DACKn is when active low is specified.

**Figure 9.28 Auto-Refresh Timing**

## (b) Self-refreshing

Self-refresh mode in which the refresh timing and refresh addresses are generated within the SDRAM. Self-refreshing is activated by setting both the RMODE bit and the RFSH bit in SDCR to 1. After starting the self-refreshing, PALL command is issued in  $T_p$  cycle after the completion of the pre-charging bank. A SELF command is then issued after inserting idle cycles of which number is specified by the WTRP1 and WTRP0 bits in CS3WSR. SDRAM cannot be accessed while in the self-refresh state. Self-refresh mode is cleared by clearing the RMODE bit to 0. After self-refresh mode has been cleared, command issuance is disabled for the number of cycles specified by the WTRC1 and WTRC0 bits in CS3WCR.

Self-refresh timing is shown in figure 9.29. Settings must be made so that self-refresh clearing and data retention are performed correctly, and auto-refreshing is performed at the correct intervals. When self-refreshing is activated from the state in which auto-refreshing is set, or when exiting standby mode other than through a power-on reset, auto-refreshing is restarted if the RFSH bit is set to 1 and the RMODE bit is cleared to 0 when self-refresh mode is cleared. If the transition from clearing of self-refresh mode to the start of auto-refreshing takes time, this time should be taken into consideration when setting the initial value of RTCNT. Making the RTCNT value 1 less than the RTCOR value will enable refreshing to be started immediately.

After self-refreshing has been set, the self-refresh state continues even if the chip standby state is entered using the LSI standby function, and is maintained even after recovery from standby mode due to an interrupt. Note that the necessary signals such as CKE must be driven even in standby state by setting the HIZCNT bit in CMNCR to 1.

When the multiplication rate for the PLL circuit is changed, the CKIO output will become unstable or will be fixed low. For details on the CKIO output, see section 4, Clock Pulse Generator (CPG). The contents of SDRAM can be retained by placing the SDRAM in the self-refresh state before changing the multiplication rate.

The self-refresh state is not cleared by a manual reset. In case of a power-on reset, the bus state controller's registers are initialized, and therefore the self-refresh state is cleared.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.

2. The waveform for DACKn is when active low is specified.

**Figure 9.29 Self-Refresh Timing**

## (9) Relationship between Refresh Requests and Bus Cycles

If a refresh request occurs during bus cycle execution, the refresh cycle must wait for the bus cycle to be completed. If a refresh request occurs while the bus is released by the bus arbitration function, the refresh will not be executed until the bus mastership is acquired. This LSI has the  $\overline{\text{REFOUT}}$  pin to request the bus while waiting for refresh execution. For  $\overline{\text{REFOUT}}$  pin function selection, see section 25, Pin Function Controller (PFC). This LSI continues to assert  $\overline{\text{REFOUT}}$  (low level) until the bus is acquired.

On receiving the asserted  $\overline{\text{REFOUT}}$  signal, the external device must negate the  $\overline{\text{BREQ}}$  signal and return the bus. If the external bus does not return the bus for a period longer than the specified refresh interval, refresh cannot be executed and the SDRAM contents may be lost.

If a new refresh request occurs while waiting for the previous refresh request, the previous refresh request is deleted. To refresh correctly, a bus cycle longer than the refresh interval or the bus mastership occupation must be prevented from occurring.

If a bus mastership is requested during self-refresh, the bus will not be released until the refresh is completed.

## (10) Low-Frequency Mode

When the SLOW bit in SDCR is set to 1, output of commands, addresses, and write data, and fetch of read data are performed at a timing suitable for operating SDRAM at a low frequency.

Figure 9.30 shows the access timing in low-frequency mode. In this mode, commands, addresses, and write data are output in synchronization with the falling edge of CKIO, which is half a cycle delayed than the normal timing. Read data is fetched at the rising edge of CKIO, which is half a cycle faster than the normal timing. This timing allows the hold time of commands, addresses, write data, and read data to be extended.

If SDRAM is operated at a high frequency with the SLOW bit set to 1, the setup time of commands, addresses, write data, and read data are not guaranteed. Take the operating frequency and timing design into consideration when making the SLOW bit setting.

**Figure 9.30 Low-Frequency Mode Access Timing**

## (11) Power-Down Mode

If the PDOWN bit in SDCR is set to 1, the SDRAM is placed in power-down mode by bringing the CKE signal to the low level in the non-access cycle. This power-down mode can effectively lower the power consumption in the non-access cycle. However, please note that if an access occurs in power-down mode, a cycle of overhead occurs because a cycle is needed to assert the CKE in order to cancel the power-down mode.

Figure 9.31 shows the access timing in power-down mode.

**Figure 9.31 Power-Down Mode Access Timing**

## (12) Power-On Sequence

In order to use SDRAM, mode setting must first be made for SDRAM after waiting for the designated pause interval after powering on. This pause interval should be provided by a power-on reset generating circuit or software.

To perform SDRAM initialization correctly, the bus state controller registers must first be set, followed by a write to the SDRAM mode register. In SDRAM mode register setting, the address signal value at that time is latched by a combination of the  $\overline{CSn}$ ,  $\overline{RASU}$ ,  $\overline{RASL}$ ,  $\overline{CASU}$ ,  $\overline{CASL}$ , and  $\overline{RD/WR}$  signals. If the value to be set is X, the bus state controller provides for value X to be written to the SDRAM mode register by performing a write to address H'FFFC4000 + X for area 2 SDRAM, and to address H'FFFC5000 + X for area 3 SDRAM. In this operation the data is ignored, but the mode write is performed as a byte-size access. To set burst read/single write, CAS latency 2 to 3, wrap type = sequential, and burst length 1 supported by the LSI, arbitrary data is written in a byte-size access to the addresses shown in table 9.18. In this time 0 is output at the external address pins of A12 or later.

**Table 9.18 Access Address in SDRAM Mode Register Write**

- Setting for Area 2

Burst read/single write (burst length 1):

| Data Bus Width | CAS Latency | Access Address | External Address Pin |
|----------------|-------------|----------------|----------------------|
| 16 bits        | 2           | H'FFFC4440     | H'0000440            |
|                | 3           | H'FFFC4460     | H'0000460            |
| 32 bits        | 2           | H'FFFC4880     | H'0000880            |
|                | 3           | H'FFFC48C0     | H'00008C0            |

Burst read/burst write (burst length 1):

| Data Bus Width | CAS Latency | Access Address | External Address Pin |
|----------------|-------------|----------------|----------------------|
| 16 bits        | 2           | H'FFFC4040     | H'0000040            |
|                | 3           | H'FFFC4060     | H'0000060            |
| 32 bits        | 2           | H'FFFC4080     | H'0000080            |
|                | 3           | H'FFFC40C0     | H'00000C0            |

- Setting for Area 3

Burst read/single write (burst length 1):

| Data Bus Width | CAS Latency | Access Address | External Address Pin |
|----------------|-------------|----------------|----------------------|
| 16 bits        | 2           | H'FFFC5440     | H'0000440            |
|                | 3           | H'FFFC5460     | H'0000460            |
| 32 bits        | 2           | H'FFFC5880     | H'0000880            |
|                | 3           | H'FFFC58C0     | H'00008C0            |

Burst read/burst write (burst length 1):

| Data Bus Width | CAS Latency | Access Address | External Address Pin |
|----------------|-------------|----------------|----------------------|
| 16 bits        | 2           | H'FFFC5040     | H'0000040            |
|                | 3           | H'FFFC5060     | H'0000060            |
| 32 bits        | 2           | H'FFFC5080     | H'0000080            |
|                | 3           | H'FFFC50C0     | H'00000C0            |

Mode register setting timing is shown in figure 9.32. A PALL command (all bank pre-charge command) is firstly issued. A REF command (auto refresh command) is then issued 8 times. An MRS command (mode register write command) is finally issued. Idle cycles, of which number is specified by the WTRP1 and WTRP0 bits in CS3WCR, are inserted between the PALL and the first REF. Idle cycles, of which number is specified by the WTRC1 and WTRC0 bits in CS3WCR, are inserted between REF and REF, and between the 8th REF and MRS. Idle cycles, of which number is one or more, are inserted between the MRS and a command to be issued next.

It is necessary to keep idle time of certain cycles for SDRAM before issuing PALL command after power-on. Refer to the manual of the SDRAM for the idle time to be needed. When the pulse width of the reset signal is longer than the idle time, mode register setting can be started immediately after the reset, but care should be taken when the pulse width of the reset signal is shorter than the idle time.

**Figure 9.32 SDRAM Mode Write Timing (Based on JEDEC)**

### (13) Low-Power SDRAM

The low-power SDRAM can be accessed using the same protocol as the normal SDRAM.

The differences between the low-power SDRAM and normal SDRAM are that partial refresh takes place that puts only a part of the SDRAM in the self-refresh state during the self-refresh function, and that power consumption is low during refresh under user conditions such as the operating temperature. The partial refresh is effective in systems in which there is data in a work area other than the specific area can be lost without severe repercussions.

The low-power SDRAM supports the extension mode register (EMRS) in addition to the mode registers as the normal SDRAM. This LSI supports issuing of the EMRS command.

The EMRS command is issued according to the conditions specified in table below. For example, if data H'0YYYYYYY is written to address H'FFFC5XX0 in longword, the commands are issued to the CS3 space in the following sequence: PALL -> REF  $\times$  8 -> MRS -> EMRS. In this case, the MRS and EMRS issue addresses are H'0000XX0 and H'YYYYYYY, respectively. If data H'1YYYYYYY is written to address H'FFFC5XX0 in longword, the commands are issued to the CS3 space in the following sequence: PALL -> MRS -> EMRS.

**Table 9.19 Output Addresses when EMRS Command Is Issued**

| Command to be Issued                | Access Address | Access Data | Write Access Size | MRS Command Issue Address | EMRS Command Issue Address |
|-------------------------------------|----------------|-------------|-------------------|---------------------------|----------------------------|
| CS2 MRS                             | H'FFFC4XX0     | H'*****     | 16 bits           | H'0000XX0                 | —                          |
| CS3 MRS                             | H'FFFC5XX0     | H'*****     | 16 bits           | H'0000XX0                 | —                          |
| CS2 MRS + EMRS<br>(with refresh)    | H'FFFC4XX0     | H'0YYYYYYY  | 32 bits           | H'0000XX0                 | H'YYYYYYY                  |
| CS3 MRS + EMRS<br>(with refresh)    | H'FFFC5XX0     | H'0YYYYYYY  | 32 bits           | H'0000XX0                 | H'YYYYYYY                  |
| CS2 MRS + EMRS<br>(without refresh) | H'FFFC4XX0     | H'1YYYYYYY  | 32 bits           | H'0000XX0                 | H'YYYYYYY                  |
| CS3 MRS + EMRS<br>(without refresh) | H'FFFC5XX0     | H'1YYYYYYY  | 32 bits           | H'0000XX0                 | H'YYYYYYY                  |

Figure 9.33 EMRS Command Issue Timing

- Deep power-down mode

The low-power SDRAM supports the deep power-down mode as a low-power consumption mode. In the partial self-refresh function, self-refresh is performed on a specific area. In the deep power-down mode, self-refresh will not be performed on any memory area. This mode is effective in systems where all of the system memory areas are used as work areas.

If the RMODE bit in the SDCR is set to 1 while the DEEP and RFSH bits in the SDCR are set to 1, the low-power SDRAM enters the deep power-down mode. If the RMODE bit is cleared to 0, the CKE signal is pulled high to cancel the deep power-down mode. Before executing an access after returning from the deep power-down mode, the power-up sequence must be re-executed.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.

2. The waveform for DACKn is when active low is specified.

**Figure 9.34 Deep Power-Down Mode Transition Timing**

### 9.5.7 Burst ROM (Clocked Asynchronous) Interface

The burst ROM (clocked asynchronous) interface is used to access a memory with a high-speed read function using a method of address switching called the burst mode or page mode. In a burst ROM (clocked asynchronous) interface, basically the same access as the normal space is performed, but the 2nd and subsequent access cycles are performed only by changing the address, without negating the RD signal at the end of the 1st cycle. In the 2nd and subsequent access cycles, addresses are changed at the falling edge of the CKIO.

For the 1st access cycle, the number of wait cycles specified by the W3 to W0 bits in CSnWCR is inserted. For the 2nd and subsequent access cycles, the number of wait cycles specified by the W1 to W0 bits in CSnWCR is inserted.

In the access to the burst ROM (clocked asynchronous), the  $\overline{BS}$  signal is asserted only to the first access cycle. An external wait input is valid only to the first access cycle.

In the single access or write access that does not perform the burst operation in the burst ROM (clocked asynchronous) interface, access timing is same as a normal space.

Table 9.20 lists a relationship between bus width, access size, and the number of bursts. Figure 9.35 shows a timing chart.

**Table 9.20 Relationship between Bus Width, Access Size, and Number of Bursts**

| Bus Width | Access Size | CSnWCR. BST[1:0] Bits | Number of Bursts | Access Count |
|-----------|-------------|-----------------------|------------------|--------------|
| 8 bits    | 8 bits      | Not affected          | 1                | 1            |
|           | 16 bits     | Not affected          | 2                | 1            |
|           | 32 bits     | Not affected          | 4                | 1            |
|           | 16 bytes    | 00                    | 16               | 1            |
|           |             | 01                    | 4                | 4            |
| 16 bits   | 8 bits      | Not affected          | 1                | 1            |
|           | 16 bits     | Not affected          | 1                | 1            |
|           | 32 bits     | Not affected          | 2                | 1            |
|           | 16 bytes    | 00                    | 8                | 1            |
|           |             | 01                    | 2                | 4            |
|           |             | 10*                   | 4                | 2            |
|           |             |                       | 2, 4, 2          | 3            |

| Bus Width | Access Size | CSnWCR. BST[1:0] Bits | Number of Bursts | Access Count |
|-----------|-------------|-----------------------|------------------|--------------|
| 32 bits   | 8 bits      | Not affected          | 1                | 1            |
|           | 16 bits     | Not affected          | 1                | 1            |
|           | 32 bits     | Not affected          | 1                | 1            |
|           | 16 bytes    | Not affected          | 4                | 1            |

Note: \* When the bus width is 16 bits, the access size is 16 bits, and the BST[1:0] bits in CSnWCR are 10, the number of bursts and access count depend on the access start address. At address H'xxx0 or H'xxx8, 4-4 burst access is performed. At address H'xxx4 or H'xxxC, 2-4-2 burst access is performed.

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.35 Burst ROM Access Timing (Clocked Asynchronous)**  
**(Bus Width = 32 Bits, 16-Byte Transfer (Number of Burst 4), Wait Cycles Inserted in First Access = 2, Wait Cycles Inserted in Second and Subsequent Access Cycles = 1)**

### 9.5.8 SRAM Interface with Byte Selection

The SRAM interface with byte selection is for access to an SRAM which has a byte-selection pin ( $\overline{\text{WEn}}$ ). This interface has 16-bit data pins and accesses SRAMs having upper and lower byte selection pins, such as UB and LB.

When the BAS bit in CSnWCR is cleared to 0 (initial value), the write access timing of the SRAM interface with byte selection is the same as that for the normal space interface. While in read access of a byte-selection SRAM interface, the byte-selection signal is output from the  $\overline{\text{WEn}}$  pin, which is different from that for the normal space interface. The basic access timing is shown in figure 9.36. In write access, data is written to the memory according to the timing of the byte-selection pin ( $\overline{\text{WEn}}$ ). For details, please refer to the Data Sheet for the corresponding memory.

If the BAS bit in CSnWCR is set to 1, the  $\overline{\text{WEn}}$  pin and RD/ $\overline{\text{WR}}$  pin timings change. Figure 9.37 shows the basic access timing. In write access, data is written to the memory according to the timing of the write enable pin (RD/ $\overline{\text{WR}}$ ). The data hold timing from RD/ $\overline{\text{WR}}$  negation to data write must be acquired by setting the HW1 and HW0 bits in CSnWCR. Figure 9.38 shows the access timing when a software wait is specified.

Note: \* The waveform for DACKn is when active low is specified.

### 9.5.9 PCMCIA Interface

With this LSI, areas 5 and 6 can be used for the IC memory card and I/O card interface defined in the JEIDA specifications version 4.2 (PCMCIA2.1 Rev. 2.1) by specifying bits TYPE[2:0] in CSnBCR (n = 5 and 6) to B'101. In addition, the bits SA[1:0] in CSnWCR (n = 5 and 6) assign the upper or lower 32 Mbytes of each area to IC memory card or I/O card interface. For example, if the bits SA1 and SA0 in CS5WCR are set to 1 and cleared to 0, respectively, the upper 32 Mbytes of area 5 are used for IC memory card interface and the lower 32 Mbytes are used for I/O card interface.

When the PCMCIA interface is used, the bus size must be specified as 8 bits or 16 bits using the bits BSZ[1:0] in CS5BCR or CS6BCR.

Figure 9.41 shows an example of connection between this LSI and a PCMCIA card. To enable hot swapping (insertion and removal of the PCMCIA card with the system power turned on), tri-state buffers must be connected between the LSI and the PCMCIA card.

In the JEIDA and PCMCIA standards, operation in big endian mode is not clearly defined. Consequently, the provided PCMCIA interface in big endian mode is available only for this LSI.

**Figure 9.41 Example of PCMCIA Interface Connection**

## (1) Basic Timing for Memory Card Interface

Figure 9.42 shows the basic timing of the PCMCIA IC memory card interface. When areas 5 and 6 are specified as the PCMCIA interface, the bus is accessed with the IC memory card interface according to the SA[1:0] bit settings in CS5WCR and CS6WCR. If the external bus frequency (CKIO) increases, the setup times and hold times for the address pins (A25 to A0), card enable signals ( $\overline{\text{CE1A}}$ ,  $\overline{\text{CE2A}}$ ,  $\overline{\text{CE1B}}$ ,  $\overline{\text{CE2B}}$ ), and write data (D15 to D0) to the  $\overline{\text{RD}}$  and  $\overline{\text{WE}}$  signals become insufficient. To prevent this error, this LSI enables the setup times and hold times for areas 5 and 6 to be specified independently, using CS5WCR and CS6WCR. In the PCMCIA interface, as in the normal space interface, a software wait or hardware wait using the  $\overline{\text{WAIT}}$  pin can be inserted. Figure 9.43 shows the PCMCIA memory bus wait timing.

**Figure 9.42 Basic Access Timing for PCMCIA Memory Card Interface**

**Figure 9.43 Wait Timing for PCMCIA Memory Card Interface**  
**(TED[3:0] = B'0010, PCW[3:0] = B'0000, TEH[3:0] = B'0001, Hardware Wait = 1)**

A port is used to generate the  $\overline{REG}$  signal that switches between the common memory and attribute memory. As shown in the example in figure 9.44, when the total memory space necessary for the common memory and attribute memory is 32 Mbytes or less, pin A24 can be used as the  $\overline{REG}$  signal to allocate a 16-Mbyte common memory space and a 16-Mbyte attribute memory space.

For 32-Mbyte capacity (I/O port is used for REG)

|                    |                                |
|--------------------|--------------------------------|
| Area 5: H'14000000 | Attribute memory/common memory |
| Area 6: H'16000000 | I/O space                      |
| Area 5: H'18000000 | Attribute memory/common memory |
| Area 6: H'1A000000 | I/O space                      |

For 16-Mbyte capacity (A24 is used for REG)

|                    |                  |
|--------------------|------------------|
| Area 5: H'14000000 | Attribute memory |
| Area 5: H'15000000 | Common memory    |
| Area 5: H'16000000 | I/O space        |
| H'17000000         |                  |
| Area 6: H'18000000 | Attribute memory |
| Area 6: H'19000000 | Common memory    |
| Area 6: H'1A000000 | I/O space        |
| H'1B000000         |                  |

**Figure 9.44 Example of PCMCIA Space Allocation (CS5WCR.SA[1:0] = B'10, CS6WCR.SA[1:0] = B'10)**

## (2) Basic Timing for I/O Card Interface

Figures 9.45 and 9.46 show the basic timing for the PCMCIA I/O card interface.

When accessing an I/O card through the PCMCIA interface, be sure to access the space as cache-disabled.

Switching between I/O card and IC memory card interfaces in the respective address spaces is accomplished by the SA[1:0] bit settings in CS5WCR and CS6WCR.

The  $\overline{\text{IOIS16}}$  pin can be used for dynamic adjustment of the width of the I/O bus in access to an I/O card via the PCMCIA interface when little endian mode has been selected. When the bus width of area 5 or 6 is set to 16 bits and the  $\overline{\text{IOIS16}}$  signal is driven high during a cycle of word-unit access to the I/O card bus, the bus width will be recognized as 8 bits and only 8 bits of data will be accessed during the current cycle of the I/O card bus. Operation will automatically continue with access to the remaining 8 bits of data.

The  $\overline{\text{IOIS16}}$  signal is sampled on falling edges of the CKIO in Tpci0 as well as all Tpci0w cycles for which the TED3 to TED0 bits are set to 1.5 cycles or more, and the  $\overline{\text{CE2A}}$  and  $\overline{\text{CE2B}}$  signals are updated after 1.5 cycles of the CKIO signal from the sampling point of Tpci0. Ensure that the  $\overline{\text{IOIS16}}$  signal is defined at all sampling points and does not change along the way.

Set the TED3 to TED0 bits to satisfy the requirement of the PC card in use with regard to setup timing from  $\overline{\text{ICIORD}}$  or  $\overline{\text{ICIOWR}}$  to  $\overline{\text{CE1}}$  or  $\overline{\text{CE2}}$ .

The basic waveforms for dynamic bus-size adjustment are shown in figure 9.46.

Since the  $\overline{\text{IOIS16}}$  signal is not supported in big endian mode, the  $\overline{\text{IOIS16}}$  signal should be fixed to the low level when big endian mode has been selected.

**Figure 9.46 Dynamic Bus-Size Adjustment Timing for PCMCIA I/O Card Interface**  
(TED[3:0] = B'0010, PCW[3:0] = B'0000, TEH[3:0] = B'0001, Hardware Wait = 1)

### 9.5.10 Burst MPX-I/O Interface

Figure 9.47 shows an example of a connection between the LSI and the burst MPX device. Figures 9.48 to 9.51 show the burst MPX space access timings.

Area 6 can be specified as the address/data multiplex I/O (MPX-I/O) interface using the TYPE2 to TYPE0 bits in CS6BCR. This MPX-I/O interface enables the LSI to be easily connected to an external memory controller chip that uses an address/data multiplexed 32-bit single bus. In this case, the address and the access size for the MPX-I/O interface are output to D25 to D0 and D31 to D29, respectively, in address cycles. For the access sizes of D31 to D29, see the description of CS6WCR for the burst MPX-I/O in section 9.4.3 (5), Burst MPX-I/O.

Address pins A25 to A0 are used to output normal addresses.

In the burst MPX-I/O interface, the bus size is fixed at 32 bits. The BSZ1 and BSZ0 bits in CS6BCR must be specified as 32 bits. In the burst MPX-I/O interface, a software wait and hardware wait using the WAIT pin can be inserted.

In read cycles, a wait cycle is inserted automatically following the address output even if the software wait insertion is specified as 0.

**Figure 9.47 Burst MPX Device Connection Example**

**(Burst Write, No Wait, CS6WCR.MPXMD = 0)**

### 9.5.11 Burst ROM (Clocked Synchronous) Interface

The burst ROM (clocked synchronous) interface is supported to access a ROM with a synchronous burst function at high speed. The burst ROM interface accesses the burst ROM in the same way as a normal space. This interface is valid only for area 0.

In the first access cycle, wait cycles are inserted. In this case, the number of wait cycles to be inserted is specified by the W3 to W0 bits in CS0WCR. In the second and subsequent cycles, the number of wait cycles to be inserted is specified by the BW1 and BW0 bits in CS0WCR.

While the burst ROM (clocked synchronous) is accessed, the  $\overline{BS}$  signal is asserted only for the first access cycle and an external wait input is also valid for the first access cycle.

If the bus width is 16 bits, the burst length must be specified as 8. If the bus width is 32 bits, the burst length must be specified as 4. The burst ROM interface does not support the 8-bit bus width for the burst ROM.

The burst ROM interface performs burst operations for all read access. For example, in a longword access over a 16-bit bus, valid 16-bit data is read two times and invalid 16-bit data is read six times. These invalid data read cycles increase the memory access time and degrade the program execution speed and DMA transfer speed. To prevent this problem, it is recommended using a 16-byte read by cache fill in the cache-enabled spaces or 16-byte read by the DMA. The burst ROM interface performs write access in the same way as normal space access.

**Figure 9.52 Burst ROM Access Timing (Clocked Synchronous)**  
**(Burst Length = 8, Wait Cycles Inserted in First Access = 2,**  
**Wait Cycles Inserted in Second and Subsequent Access Cycles = 1)**

### 9.5.12 Wait between Access Cycles

As the operating frequency of LSIs becomes higher, the off-operation of the data buffer often collides with the next data access when the read operation from devices with slow access speed is completed. As a result of these collisions, the reliability of the device is low and malfunctions may occur. A function that avoids data collisions by inserting idle (wait) cycles between continuous access cycles has been newly added.

The number of wait cycles between access cycles can be set by the WM bit in CSnWCR, bits IWW2 to IWW0, IWRWD2 to IWRWD0, IWRWS2 to IWRWS0, IWRRD2 to IWRRD0, and IWRRS2 to IWRRS 0 in CSnBCR, and bits DMAIW2 to DMAIW0 and DMAIWA in CMNCR. The conditions for setting the idle cycles between access cycles are shown below.

1. Continuous access cycles are write-read or write-write
2. Continuous access cycles are read-write for different spaces
3. Continuous access cycles are read-write for the same space
4. Continuous access cycles are read-read for different spaces
5. Continuous access cycles are read-read for the same space
6. Data output from an external device caused by DMA single address transfer is followed by data output from another device that includes this LSI (DMAIWA = 0)
7. Data output from an external device caused by DMA single address transfer is followed by any type of access (DMAIWA = 1)

For the specification of the number of idle cycles between access cycles described above, refer to the description of each register.

Besides the idle cycles between access cycles specified by the registers, idle cycles must be inserted to interface with the internal bus or to obtain the minimum pulse width for a multiplexed pin ( $\overline{\text{WEn}}$ ). The following gives detailed information about the idle cycles and describes how to estimate the number of idle cycles.

The number of idle cycles on the external bus from  $\overline{\text{CSn}}$  negation to  $\overline{\text{CSn}}$  or  $\overline{\text{CSm}}$  assertion is described below. Here,  $\overline{\text{CSn}}$  and  $\overline{\text{CSm}}$  also include  $\overline{\text{CE2A}}$  and  $\overline{\text{CE2B}}$  for PCMCIA.

There are eight conditions that determine the number of idle cycles on the external bus as shown in table 9.21. The effects of these conditions are shown in figure 9.53.

**Table 9.21 Conditions for Determining Number of Idle Cycles**

| No. | Condition                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Range   | Note                                                                                                                                                                                                                                              |
|-----|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [1] | DMAIW[2:0] in CMNCR          | These bits specify the number of idle cycles for DMA single address transfer. This condition is effective only for single address transfer and generates idle cycles after the access is completed.                                                                                                                                                                                                                                                                                                                                     | 0 to 12 | When 0 is specified for the number of idle cycles, the DACK signal may be asserted continuously. This causes a discrepancy between the number of cycles detected by the device with DACK and the DMAC transfer count, resulting in a malfunction. |
| [2] | IW***[2:0] in CSnBCR         | These bits specify the number of idle cycles for access other than single address transfer. The number of idle cycles can be specified independently for each combination of the previous and next cycles. For example, in the case where reading CS1 space followed by reading other CS space, the bits IWRRD[2:0] in CS1BCR should be set to B'100 to specify six or more idle cycles. This condition is effective only for access cycles other than single address transfer and generates idle cycles after the access is completed. | 0 to 12 | Do not set 0 for the number of idle cycles between memory types which are not allowed to be accessed successively.                                                                                                                                |
| [3] | SDRAM-related bits in CSnWCR | These bits specify precharge completion and startup wait cycles and idle cycles between commands for SDRAM access. This condition is effective only for SDRAM access and generates idle cycles after the access is completed                                                                                                                                                                                                                                                                                                            | 0 to 3  | Specify these bits in accordance with the specification of the target SDRAM.                                                                                                                                                                      |
| [4] | WM in CSnWCR                 | This bit enables or disables external WAIT pin input for the memory types other than SDRAM. When this bit is cleared to 0 (external $\overline{\text{WAIT}}$ enabled), one idle cycle is inserted to check the external $\overline{\text{WAIT}}$ pin input after the access is completed. When this bit is set to 1 (disabled), no idle cycle is generated.                                                                                                                                                                             | 0 or 1  |                                                                                                                                                                                                                                                   |

| No. | Condition                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                | Range       | Note                                                                                                                                                                                                                                                                                                                                 |
|-----|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [5] | Read data transfer cycle                   | One idle cycle is inserted after a read access is completed. This idle cycle is not generated for the first or middle cycles in divided access cycles. This is neither generated when the HW[1:0] bits in CSnWCR are not B'00.                                                                                                                                                                                                                             | 0 or 1      | One idle cycle is always generated after a read cycle with SDRAM or PCMCIA interface.                                                                                                                                                                                                                                                |
| [6] | Internal bus idle cycles, etc.             | External bus access requests from the CPU or DMAC and their results are passed through the internal bus. The external bus enters idle state during internal bus idle cycles or while a bus other than the external bus is being accessed. This condition is not effective for divided access cycles, which are generated by the BSC when the access size is larger than the external data bus width.                                                       | 0 or larger | The number of internal bus idle cycles may not become 0 depending on the $\phi:B\phi$ clock ratio. Tables 9.22 and 9.23 show the relationship between the clock ratio and the minimum number of internal bus idle cycles.                                                                                                            |
| [7] | Write data wait cycles                     | During write access, a write cycle is executed on the external bus only after the write data becomes ready. This write data wait period generates idle cycles before the write cycle. Note that when the previous cycle is a write cycle and the internal bus idle cycles are shorter than the previous write cycle, write data can be prepared in parallel with the previous write cycle and therefore, no idle cycle is generated (write buffer effect). | 0 or 1      | For write → write or write → read access cycles, successive access cycles without idle cycles are frequently available due to the write buffer effect described in the left column. If successive access cycles without idle cycles are not allowed, specify the minimum number of idle cycles between access cycles through CSnBCR. |
| [8] | Idle cycles between different memory types | To ensure the minimum pulse width on the signal-multiplexed pins, idle cycles may be inserted before access after memory types are switched. For some memory types, idle cycles are inserted even when memory types are not switched.                                                                                                                                                                                                                      | 0 to 2.5    | The number of idle cycles depends on the target memory types. See table 9.24.                                                                                                                                                                                                                                                        |

In the above conditions, a total of four conditions, that is, condition [1] or [2] (either one is effective), condition [3] or [4] (either one is effective), a set of conditions [5] to [7] (these are generated successively, and therefore the sum of them should be taken as one set of idle cycles), and condition [8] are generated at the same time. The maximum number of idle cycles among these four conditions become the number of idle cycles on the external bus. To ensure the minimum idle cycles, be sure to make register settings for condition [1] or [2].

Figure 9.53 Idle Cycle Conditions

**Table 9.22 Minimum Number of Idle Cycles on Internal Bus (CPU Operation)**

| CPU Operation | Clock Ratio ( $I\phi:B\phi$ ) |     |     |     |     |     |
|---------------|-------------------------------|-----|-----|-----|-----|-----|
|               | 8:1                           | 6:1 | 4:1 | 3:1 | 2:1 | 1:1 |
| Write → write | 1                             | 1   | 2   | 2   | 2   | 3   |
| Write → read  | 0                             | 0   | 0   | 0   | 0   | 1   |
| Read → write  | 1                             | 1   | 2   | 2   | 2   | 3   |
| Read → read   | 0                             | 0   | 0   | 0   | 0   | 1   |

**Table 9.23 Minimum Number of Idle Cycles on Internal Bus (DMAC Operation)**

| DMAC Operation | Transfer Mode |                |
|----------------|---------------|----------------|
|                | Dual Address  | Single Address |
| Write → write  | 0             | 2              |
| Write → read   | 0 or 2        | 0              |
| Read → write   | 0             | 0              |
| Read → read    | 0             | 2              |

- Notes: 1. The write → write and read → read columns in dual address transfer indicate the cycles in the divided access cycles.
2. For the write → read cycles in dual address transfer, 0 means different channels are activated successively and 2 means when the same channel is activated successively.
3. The write → read and read → write columns in single address transfer indicate the case when different channels are activated successively. The "write" means transfer from a device with DACK to external memory and the "read" means transfer from external memory to a device with DACK.

**Table 9.24 Number of Idle Cycles Inserted between Access Cycles to Different Memory Types**

| Previous Cycle                   | Next Cycle        |                             |                   |                              |                              |                   |                                      |                   |                   |                            |

| Burst ROM<br>(synchronous)       | 0                 | 0                           | 1                 | 0                            | 1                            | 1                 | 1.5                                  | 0                 | 0                 | 0                          |

- Notes: 1. The number of idle cycles is determined by the setting of the CSnWCR.HW[1:0] bits on the previous cycle. The number of idle cycles will be the number shown at the left when HW[1:0] ≠ B'00, will be the number shown at the right when HW[1:0] = B'00. Also, for CSn spaces for which the CSnWCR.HW[1:0] bits do not exist, the number of idle cycles shown at the right will be used.
2. The number of idle cycles is determined by the setting of the CSnWCR.TEH[3:0] bits on the previous cycle. The number of idle cycles will be the number shown at the left when TEH[3:0] ≠ B'0000, will be the number shown at the right when TEH[3:0] = B'0000.

Figure 9.54 shows sample estimation of idle cycles between access cycles. In the actual operation, the idle cycles may become shorter than the estimated value due to the write buffer effect or may become longer due to internal bus idle cycles caused by stalling in the pipeline due to CPU instruction execution or CPU register conflicts. Please consider these errors when estimating the idle cycles.

#### Sample Estimation of Idle Cycles between Access Cycles

This example estimates the idle cycles for data transfer from the CS1 space to CS2 space by CPU access. Transfer is repeated in the following order: CS1 read → CS1 read → CS2 write → CS2 write → CS1 read → ...

##### • Conditions

The bits for setting the idle cycles between access cycles in CS1BCR and CS2BCR are all set to 0.

In CS1WCR and CS2WCR, the WM bit is set to 1 (external WAIT pin disabled) and the HW[1:0] bits are set to 00 (CS negation is not extended).

$\phi:B\phi$  is set to 4:1, and no other processing is done during transfer.

For both the CS1 and CS2 spaces, normal SRAM devices are connected, the bus width is 32 bits, and access size is also 32 bits.

The idle cycles generated under each condition are estimated for each pair of access cycles. In the following table, R indicates a read cycle and W indicates a write cycle.

| Condition             | R → R | R → W | W → W | W → R | Note                                                                                                                                                                                                                                                     |
|-----------------------|-------|-------|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [1] or [2]            | 0     | 0     | 0     | 0     | CSnBCR is set to 0.                                                                                                                                                                                                                                      |
| [3] or [4]            | 0     | 0     | 0     | 0     | The WM bit is set to 1.                                                                                                                                                                                                                                  |

| [6]                   | 0     | 2     | 2     | 0     | See the $\phi:B\phi = 4:1$ columns in table 9.22.                                                                                                                                                                                                        |
| [7]                   | 0     | 1     | 0     | 0     | No idle cycle is generated for the second time due to the write buffer effect.                                                                                                                                                                           |
| [5] + [6] + [7]       | 1     | 4     | 2     | 0     |                                                                                                                                                                                                                                                          |
| [8]                   | 0     | 0     | 0     | 0     | Value for SRAM → SRAM access                                                                                                                                                                                                                             |
| Estimated idle cycles | 1     | 4     | 2     | 0     | Maximum value among conditions [1] or [2], [3] or [4], [5] + [6] + [7], and [8]                                                                                                                                                                          |
| Actual idle cycles    | 1     | 4     | 2     | 1     | The estimated value does not match the actual value in the W → R cycles because the internal idle cycles due to condition [6] is estimated as 0 but actually an internal idle cycle is generated due to execution of a loop condition check instruction. |

**Figure 9.54 Comparison between Estimated Idle Cycles and Actual Value**

### 9.5.13 Bus Arbitration

The bus arbitration of this LSI has the bus mastership in the normal state and releases the bus mastership after receiving a bus request from another device.

Bus mastership is transferred at the boundary of bus cycles. Namely, bus mastership is released immediately after receiving a bus request when a bus cycle is not being performed. The release of bus mastership is delayed until the bus cycle is complete when a bus cycle is in progress. Even when from outside the LSI it looks like a bus cycle is not being performed, a bus cycle may be performing internally, started by inserting wait cycles between access cycles. Therefore, it cannot be immediately determined whether or not bus mastership has been released by looking at the  $\overline{\text{CSn}}$  signal or other bus control signals. The states that do not allow bus mastership release are shown below.

1. 16-byte transfer because of a cache miss
2. During write-back operation for the cache
3. Between the read and write cycles of a TAS instruction
4. Multiple bus cycles generated when the data bus width is smaller than the access size (for example, between bus cycles when longword access is made to a memory with a data bus width of 8 bits)
5. 16-byte transfer by the DMAC
6. Setting the BLOCK bit in CMNCR to 1
7. 16-byte to 128-byte transfer by the LCDC

Moreover, by using DPRTY bit in CMNCR, whether the bus mastership request is received or not can be selected during DMAC burst transfer.

The LSI has the bus mastership until a bus request is received from another device. Upon acknowledging the assertion (low level) of the external bus request signal  $\overline{\text{BREQ}}$ , the LSI releases the bus at the completion of the current bus cycle and asserts the  $\overline{\text{BACK}}$  signal. After the LSI acknowledges the negation (high level) of the  $\overline{\text{BREQ}}$  signal that indicates the external device has released the bus, it negates the  $\overline{\text{BACK}}$  signal and resumes the bus usage.

With the SDRAM interface, all bank pre-charge commands (PALLs) are issued when active banks exist and the bus is released after completion of a PALL command.

The bus sequence is as follows. The address bus and data bus are placed in a high-impedance state synchronized with the rising edge of CKIO. The bus mastership enable signal is asserted 0.5 cycles after the above timing, synchronized with the falling edge of CKIO. The bus control signals ( $\overline{\text{BS}}$ ,  $\overline{\text{CSn}}$ ,  $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASU}}$ ,  $\overline{\text{CASL}}$ ,  $\overline{\text{CKE}}$ ,  $\overline{\text{DQMxx}}$ ,  $\overline{\text{WEn}}$ ,  $\overline{\text{RD}}$ , and  $\overline{\text{RD/WR}}$ ) are placed in the high-impedance state at subsequent rising edges of CKIO. Bus request signals are sampled at

the falling edge of CKIO. Note that  $\overline{\text{CKE}}$ ,  $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASU}}$ , and  $\overline{\text{CASL}}$  can be continued to be driven at the previous value even in the bus-released state by setting the HIZCNT bit in CMNCR.

The sequence for reclaiming the bus mastership from an external device is described below. 1.5 cycles after the negation of  $\overline{\text{BREQ}}$  is detected at the falling edge of CKIO, the bus control signals are driven high. The bus acknowledge signal is negated at the next falling edge of the clock. The fastest timing at which actual bus cycles can be resumed after bus control signal assertion is at the rising edge of the CKIO where address and data signals are driven. Figure 9.55 shows the bus arbitration timing.

When it is necessary to refresh SDRAM while releasing the bus mastership, the bus mastership should be returned using the  $\overline{\text{REFOUT}}$  signal. For details on the selection of  $\overline{\text{REFOUT}}$ , see section 25, Pin Function Controller (PFC). The  $\overline{\text{REFOUT}}$  signal is kept asserting at low level until the bus mastership is acquired. The  $\overline{\text{BREQ}}$  signal is negated by asserting the  $\overline{\text{REFOUT}}$  signal and the bus mastership is returned from the external device. If the bus mastership is not returned for a refreshing period or longer, the contents of SDRAM cannot be guaranteed because a refreshing cannot be executed.

While releasing the bus mastership, the SLEEP instruction (to enter sleep mode, deep standby mode, or software standby mode), as well as a manual reset, cannot be executed until the LSI obtains the bus mastership.

The  $\overline{\text{BREQ}}$  input signal is ignored in software standby mode or deep standby mode and the  $\overline{\text{BACK}}$  output signal is placed in the high impedance state. If the bus mastership request is required in this state, the bus mastership must be released by pulling down the  $\overline{\text{BACK}}$  pin to enter software standby mode or deep standby mode.

The bus mastership release ( $\overline{\text{BREQ}}$  signal for high level negation) after the bus mastership request ( $\overline{\text{BREQ}}$  signal for low level assertion) must be performed after the bus usage permission ( $\overline{\text{BACK}}$  signal for low level assertion). If the  $\overline{\text{BREQ}}$  signal is negated before the  $\overline{\text{BACK}}$  signal is asserted, only one cycle of the  $\overline{\text{BACK}}$  signal is asserted depending on the timing of the  $\overline{\text{BREQ}}$  signal to be negated and this may cause a bus contention between the external device and the LSI.

**Figure 9.55 Bus Arbitration Timing**

### 9.5.14 Others

#### (1) Reset

The bus state controller (BSC) can be initialized completely only at power-on reset. At power-on reset, all signals are negated and data output buffers are turned off regardless of the bus cycle state after the internal reset is synchronized with the internal clock. All control registers are initialized. In software standby, sleep, and manual reset, control registers of the bus state controller are not initialized. At manual reset, only the current bus cycle being executed is completed. Since the RTCNT continues counting up during manual reset signal assertion, a refresh request occurs to initiate the refresh cycle.

#### (2) Access from the Side of the LSI Internal Bus Master

There are three types of LSI internal buses: a CPU bus, internal bus, and peripheral bus. The CPU and cache memory are connected to the CPU bus. Internal bus masters other than the CPU and bus state controller are connected to the internal bus. Low-speed peripheral modules are connected to the peripheral bus. Internal memories other than the cache memory are connected bidirectionally to the CPU bus and internal bus. Access from the CPU bus to the internal bus is enabled but access from the internal bus to the cache bus is disabled. This gives rise to the following problems.

On-chip bus masters such as DMAC other than the CPU can access internal memory other than the cache memory but cannot access the cache memory. If an on-chip bus master other than the CPU writes data to an external memory other than the cache, the contents of the external memory may differ from that of the cache memory. To prevent this problem, if the external memory whose contents is cached is written by an on-chip bus master other than the CPU, the corresponding cache memory should be purged by software.

In a cache-enabled space, if the CPU initiates read access, the cache is searched. If the cache stores data, the CPU latches the data and completes the read access. If the cache does not store data, the CPU performs four contiguous longword read cycles to perform cache fill operations via the

internal bus. If a cache miss occurs in byte or word operand access or at a branch to an odd word boundary ( $4n + 2$ ), the CPU performs four contiguous longword access cycles to perform a cache fill operation on the external interface. For a cache-disabled space, the CPU performs access according to the actual access addresses. For an instruction fetch to an even word boundary ( $4n$ ), the CPU performs longword access. For an instruction fetch to an odd word boundary ( $4n + 2$ ), the CPU performs word access.

For a read cycle of an on-chip peripheral module, the cycle is initiated through the internal bus and peripheral bus. The read data is sent to the CPU via the peripheral bus, internal bus, and CPU bus.

In a write cycle for the cache-enabled space, the write cycle operation differs according to the cache write methods.

In write-back mode, the cache is first searched. If data is detected at the address corresponding to the cache, the data is then re-written to the cache. In the actual memory, data will not be re-written until data in the corresponding address is re-written. If data is not detected at the address corresponding to the cache, the cache is modified. In this case, data to be modified is first saved to the internal buffer, 16-byte data including the data corresponding to the address is then read, and data in the corresponding access of the cache is finally modified. Following these operations, a write-back cycle for the saved 16-byte data is executed.

In write-through mode, the cache is first searched. If data is detected at the address corresponding to the cache, the data is re-written to the cache simultaneously with the actual write via the internal bus. If data is not detected at the address corresponding to the cache, the cache is not modified but an actual write is performed via the internal bus.

Since the bus state controller (BSC) incorporates a one-stage write buffer, the BSC can execute an access via the internal bus before the previous external bus cycle is completed in a write cycle. If the on-chip module is read or written after the external low-speed memory is written, the on-chip module can be accessed before the completion of the external low-speed memory write cycle.

In read cycles, the CPU is placed in the wait state until read operation has been completed. To continue the process after the data write to the device has been completed, perform a dummy read to the same address to check for completion of the write before the next process to be executed.

The write buffer of the BSC functions in the same way for an access by a bus master other than the CPU such as the DMAC. Accordingly, to perform dual address DMA transfers, the next read cycle is initiated before the previous write cycle is completed. Note, however, that if both the DMA source and destination addresses exist in external memory space, the next write cycle will not be initiated until the previous write cycle is completed.

Changing the registers in the BSC while the write buffer is operating may disrupt correct write access. Therefore, do not change the registers in the BSC immediately after a write access. If this change becomes necessary, do it after executing a dummy read of the write data.

### (3) On-Chip Peripheral Module Access

To access an on-chip module register, two or more peripheral module clock ( $P\phi$ ) cycles are required. Care must be taken in system design.

When the CPU writes data to the internal peripheral registers, the CPU performs the succeeding instructions without waiting for the completion of writing to registers.

For example, a case is described here in which the system is transferring to the software standby mode for power savings. To make this transition, the SLEEP instruction must be performed after setting the STBY bit in the STBCR register to 1. However a dummy read of the STBCR register is required before executing the SLEEP instruction. If a dummy read is omitted, the CPU executes the SLEEP instruction before the STBY bit is set to 1, thus the system enters sleep mode not software standby mode. A dummy read of the STBCR register is indispensable to complete writing to the STBY bit.

To reflect the change by internal peripheral registers while performing the succeeding instructions, execute a dummy read of registers to which write instruction is given and then perform the succeeding instructions.

## 9.6 Usage Notes

### 9.6.1 Note when using both the bus arbitration function and the software standby mode

When using both the bus arbitration function and the software standby mode, set the bus arbitration function disable (set the BLOCK bit in CMNCR to 1) before entering the software standby mode, and set the bus arbitration function enable (set the BLOCK bit in CMNCR to 0) after cancelling the software standby mode. If the LSI enter the software standby mode in the case that the BLOCK bit is set to 0,  $\overline{BACK}$  pin outputs low for 1 bus clock ( $B\phi$ ) cycle after canceling the software standby mode even though  $\overline{BREQ}$  input is high.

## Section 10 Direct Memory Access Controller (DMAC)

The DMAC can be used in place of the CPU to perform high-speed transfers between external devices that have DACK (transfer request acknowledge signal), external memory, on-chip memory, memory-mapped external devices, and on-chip peripheral modules.

### 10.1 Features

- Number of channels: Eight channels (channels 0 to 7) selectable  
Four channels (channels 0 to 3) can receive external requests.
- 4-Gbyte physical address space
- Data transfer unit is selectable: Byte, word (two bytes), longword (four bytes), and 16 bytes (longword  $\times$  4)
- Maximum transfer count: 16,777,216 transfers (24 bits)
- Address mode: Dual address mode and single address mode are supported.
- Transfer requests
  - External request
  - On-chip peripheral module request
  - Auto request

The following modules can issue on-chip peripheral module requests.

- Eight SCIF sources, eight IIC3 sources, one A/D converter source, five MTU2 sources, two CMT sources, two USB sources, two FLCTL sources, two RCAN-TL1 sources, four SSI sources, four SSU sources
- Selectable bus modes
  - Cycle steal mode (normal mode and intermittent mode)
  - Burst mode
- Selectable channel priority levels: The channel priority levels are selectable between fixed mode and round-robin mode.
- Interrupt request: An interrupt request can be sent to the CPU on completion of half- or full-data transfer. Through the HE and HIE bits in CHCR, an interrupt is specified to be issued to the CPU when half of the initially specified DMA transfer is completed.

- External request detection: There are following four types of DREQ input detection.
  - Low level detection
  - High level detection
  - Rising edge detection
  - Falling edge detection
- Transfer request acknowledge and transfer end signals: Active levels for DACK and TEND can be set independently.
- Support of reload functions in DMA transfer information registers: DMA transfer using the same information as the current transfer can be repeated automatically without specifying the information again. Modifying the reload registers during DMA transfer enables next DMA transfer to be done using different transfer information. The reload function can be enabled or disabled independently in each channel or reload register.

Figure 10.1 shows the block diagram of the DMAC.

**Figure 10.1 Block Diagram of DMAC**

## 10.2 Input/Output Pins

The external pins for DMAC are described below. Table 10.1 lists the configuration of the pins that are connected to external bus. DMAC has pins for four channels (channels 0 to 3) for external bus use.

**Table 10.1 Pin Configuration**

| Channel | Name                             | Abbreviation | I/O | Function                                                                     |
|---------|----------------------------------|--------------|-----|------------------------------------------------------------------------------|
| 0       | DMA transfer request             | DREQ0        | I   | DMA transfer request input from an external device to channel 0              |
|         | DMA transfer request acknowledge | DACK0        | O   | DMA transfer request acknowledge output from channel 0 to an external device |
| 1       | DMA transfer request             | DREQ1        | I   | DMA transfer request input from an external device to channel 1              |
|         | DMA transfer request acknowledge | DACK1        | O   | DMA transfer request acknowledge output from channel 1 to an external device |
| 2       | DMA transfer request             | DREQ2        | I   | DMA transfer request input from an external device to channel 2              |
|         | DMA transfer request acknowledge | DACK2        | O   | DMA transfer request acknowledge output from channel 2 to an external device |
| 3       | DMA transfer request             | DREQ3        | I   | DMA transfer request input from an external device to channel 3              |
|         | DMA transfer request acknowledge | DACK3        | O   | DMA transfer request acknowledge output from channel 3 to an external device |
| 0       | DMA transfer end                 | TEND0        | O   | DMA transfer end output for channel 0                                        |
| 1       | DMA transfer end                 | TEND1        | O   | DMA transfer end output for channel 1                                        |

## 10.3 Register Descriptions

The DMAC has the registers listed in table 10.2. There are four control registers and three reload registers for each channel, and one common control register is used by all channels. In addition, there is one extension resource selector per two channels. Each channel number is expressed in the register names, as in SAR\_0 for SAR in channel 0.

**Table 10.2 Register Configuration**

| Channel | Register Name                             | Abbreviation | R/W               | Initial Value | Address    | Access Size |
|---------|-------------------------------------------|--------------|-------------------|---------------|------------|-------------|
| 0       | DMA source address register_0             | SAR0         | R/W               | H'00000000    | H'FFFE1000 | 16, 32      |
|         | DMA destination address register_0        | DAR0         | R/W               | H'00000000    | H'FFFE1004 | 16, 32      |
|         | DMA transfer count register_0             | DMATCR0      | R/W               | H'00000000    | H'FFFE1008 | 16, 32      |
|         | DMA channel control register_0            | CHCR0        | R/W* <sup>1</sup> | H'00000000    | H'FFFE100C | 8, 16, 32   |
|         | DMA reload source address register_0      | RSAR0        | R/W               | H'00000000    | H'FFFE1100 | 16, 32      |
|         | DMA reload destination address register_0 | RDAR0        | R/W               | H'00000000    | H'FFFE1104 | 16, 32      |
|         | DMA reload transfer count register_0      | RDMATCR0     | R/W               | H'00000000    | H'FFFE1108 | 16, 32      |
| 1       | DMA source address register_1             | SAR1         | R/W               | H'00000000    | H'FFFE1010 | 16, 32      |
|         | DMA destination address register_1        | DAR1         | R/W               | H'00000000    | H'FFFE1014 | 16, 32      |
|         | DMA transfer count register_1             | DMATCR1      | R/W               | H'00000000    | H'FFFE1018 | 16, 32      |

- Notes: 1. For the HE and TE bits in CHCRn, only 0 can be written to clear the flags after 1 is read.
2. For the AE and NMIF bits in DMAOR, only 0 can be written to clear the flags after 1 is read.

### 10.3.1 DMA Source Address Registers (SAR)

The DMA source address registers (SAR) are 32-bit readable/writable registers that specify the source address of a DMA transfer. During a DMA transfer, these registers indicate the next source address. When the data of an external device with DACK is transferred in single address mode, SAR is ignored.

To transfer data in word (2-byte), longword (4-byte), or 16-byte unit, specify the address with 2-byte, 4-byte, or 16-byte address boundary respectively.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

### 10.3.2 DMA Destination Address Registers (DAR)

The DMA destination address registers (DAR) are 32-bit readable/writable registers that specify the destination address of a DMA transfer. During a DMA transfer, these registers indicate the next destination address. When the data of an external device with DACK is transferred in single address mode, DAR is ignored.

To transfer data in word (2-byte), longword (4-byte), or 16-byte unit, specify the address with 2-byte, 4-byte, or 16-byte address boundary respectively.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

### 10.3.3 DMA Transfer Count Registers (DMATCR)

The DMA transfer count registers (DMATCR) are 32-bit readable/writable registers that specify the number of DMA transfers. The transfer count is 1 when the setting is H'00000001, 16,777,215 when H'00FFFFFF is set, and 16,777,216 (the maximum) when H'00000000 is set. During a DMA transfer, these registers indicate the remaining transfer count.

The upper eight bits of DMATCR are always read as 0, and the write value should always be 0. To transfer data in 16 bytes, one 16-byte transfer (128 bits) counts one.

|                |    |    |    |    |    |    |    |    |     |     |     |     |     |     |     |     |
|----------------|----|----|----|----|----|----|----|----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |

### 10.3.4 DMA Channel Control Registers (CHCR)

The DMA channel control registers (CHCR) are 32-bit readable/writable registers that control the DMA transfer mode.

The DO, AM, AL, DL, and DS bits which specify the DREQ and DACK external pin functions can be read and written to in channels 0 to 3, but they are reserved in channels 4 to 7. The TL bit which specifies the TEND external pin function can be read and written to in channels 0 and 1, but it is reserved in channels 2 to 7.

| 0   | DE       | 0             | R/W                 | <p>DMA Enable</p> <p>Enables or disables the DMA transfer. In auto request mode, DMA transfer starts by setting the DE bit and DME bit in DMAOR to 1. In this case, all of the bits TE, NMIF in DMAOR, and AE must be 0. In an external request or peripheral module request, DMA transfer starts if DMA transfer request is generated by the devices or peripheral modules after setting the bits DE and DME to 1. If the DREQ signal is detected by low/high level in external request mode, or in peripheral module request mode, the NMIF bit and the AE bit must be 0 if the TEMASK bit is 1. If the TEMASK bit is 0, the TE bit must also be 0. If the DREQ signal is detected by a rising/falling edge in external request mode, all of the bits TE, NMIF, and AE must be 0 as in the case of auto request mode. Clearing the DE bit to 0 can terminate the DMA transfer.</p> <p>0: DMA transfer disabled</p> <p>1: DMA transfer enabled</p> |

Notes: 1. Only 0 can be written to clear the flag after 1 is read.

2. If the flag is read at the same timing it is set to 1, the read data will be 0, but the internal state may be the same as reading 1. Therefore, if 0 is written to the flag, the flag will be cleared to 0 because the internal state is the same as when writing 0 after reading 1. For details, refer to section 10.5.5, Notes on Using Flag Bits.

### 10.3.5 DMA Reload Source Address Registers (RSAR)

The DMA reload source address registers (RSAR) are 32-bit readable/writable registers.

When the SAR reload function is enabled, the RSAR value is written to the source address register (SAR) at the end of the current DMA transfer. In this case, a new value for the next DMA transfer can be preset in RSAR during the current DMA transfer. When the SAR reload function is disabled, RSAR is ignored.

To transfer data in word (2-byte), longword (4-byte), or 16-byte unit, specify the address with 2-byte, 4-byte, or 16-byte address boundary respectively.

### 10.3.6 DMA Reload Destination Address Registers (RDAR)

The DMA reload destination address registers (RDAR) are 32-bit readable/writable registers.

When the DAR reload function is enabled, the RDAR value is written to the destination address register (DAR) at the end of the current DMA transfer. In this case, a new value for the next DMA transfer can be preset in RDAR during the current DMA transfer. When the DAR reload function is disabled, RDAR is ignored.

To transfer data in word (2-byte), longword (4-byte), or 16-byte unit, specify the address with 2-byte, 4-byte, or 16-byte address boundary respectively.

### 10.3.7 DMA Reload Transfer Count Registers (RDMATCR)

The DMA reload transfer count registers (RDMATCR) are 32-bit readable/writable registers.

When the SAR/DAR reload function is enabled, the RDMATCR value is written to the transfer count register (DMATCR) at the end of the current DMA transfer. In this case, a new value for the next DMA transfer can be preset in RDMATCR during the current DMA transfer. When the SAR/DAR reload function is disabled, RDMATCR is ignored.

The upper eight bits of RDMATCR are always read as 0, and the write value should always be 0.

As in DMATCR, the transfer count is 1 when the setting is H'00000001, 16,777,215 when H'00FFFFFF is set, and 16,777,216 (the maximum) when H'00000000 is set. To transfer data in 16 bytes, one 16-byte transfer (128 bits) counts one.

### 10.3.8 DMA Operation Register (DMAOR)

The DMA operation register (DMAOR) is a 16-bit readable/writable register that specifies the priority level of channels at the DMA transfer. This register also shows the DMA transfer status.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | DME      | 0             | R/W | <p><b>DMA Master Enable</b></p> <p>Enables or disables DMA transfer on all channels. If the DME bit and DE bit in CHCR are set to 1, DMA transfer is enabled.</p> <p>However, transfer is enabled only when the TE bit in CHCR of the transfer corresponding channel, the NMIF bit in DMAOR, and the AE bit are all cleared to 0. Clearing the DME bit to 0 can terminate the DMA transfer on all channels.</p> <p>0: DMA transfer is disabled on all channels<br/>1: DMA transfer is enabled on all channels</p> |

Notes: 1. Only 0 can be written to clear the flag after 1 is read.

2. If the flag is read at the same timing it is set to 1, the read data will be 0, but the internal state may be the same as reading 1. Therefore, if 0 is written to the flag, the flag will be cleared to 0 because the internal state is the same as when writing 0 after reading 1. For details, refer to section 10.5.5, Notes on Using Flag Bits.

If the priority mode bits are modified after a DMA transfer, the channel priority is initialized. If fixed mode 2 is specified, the channel priority is specified as CH0 > CH4 > CH1 > CH5 > CH2 > CH6 > CH3 > CH7. If fixed mode 1 is specified, the channel priority is specified as CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7. If the round-robin mode is specified, the transfer end channel is reset.

Table 10.3 show the priority change in each mode (modes 0 to 2) specified by the priority mode bits. In each priority mode, the channel priority to accept the next transfer request may change in up to three ways according to the transfer end channel.

For example, when the transfer end channel is channel 1, the priority of the channel to accept the next transfer request is specified as CH2 > CH3 > CH0 > CH1 > CH4 > CH5 > CH6 > CH7. When the transfer end channel is any one of the channels 4 to 7, round-robin will not be applied and the priority level is not changed at the end of transfer in the channels 4 to 7.

The DMAC internal operation for an address error is as follows:

- No address error: Read (source to DMAC) → Write (DMAC to destination)
- Address error in source address: Nop → Nop
- Address error in destination address: Read → Nop

|                              | Transfer End | Priority Mode Bits |       | Priority Level at the End of Transfer |     |     |     |     |     |     |     |

### 10.3.9 DMA Extension Resource Selectors 0 to 3 (DMARS0 to DMARS3)

The DMA extension resource selectors (DMARS) are 16-bit readable/writable registers that specify the source of the DMA transfer request from peripheral modules in each channel. DMARS0 is for channels 0 and 1, DMARS1 is for channels 2 and 3, DMARS2 is for channels 4 and 5, and DMARS3 is for channels 6 and 7. Table 10.4 shows the specifiable combinations.

DMARS can specify the following transfer request sources: eight SCIF sources, eight IIC3 sources, one A/D converter source, five MTU2 sources, and two CMT sources, two USB sources, two FLCTL sources, four SSI sources, four SSU sources.

Two RCAN-TL sources do not need to be specified by these registers, for these two sources can be specified using the RS3 to RS0 bits in the DMA channel control register (CHCR).

When MID or RID other than the values listed in table 10.4 is set, the operation of this LSI is not guaranteed. The transfer request from DMARS is valid only when the resource select bits (RS3 to RS0) in CHCR0 to CHCR7 have been set to B'1000. Otherwise, even if DMARS has been set, the transfer request source is not accepted.

## 10.4 Operation

When there is a DMA transfer request, the DMAC starts the transfer according to the predetermined channel priority order; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in three modes: auto request, external request, and on-chip peripheral module request. In bus mode, the burst mode or the cycle steal mode can be selected.

### 10.4.1 Transfer Flow

After the DMA source address registers (SAR), DMA destination address registers (DAR), DMA transfer count registers (DMATCR), DMA channel control registers (CHCR), DMA operation register (DMAOR), three reload registers (RSAR, RDAR, RDMATCR) and DMA extension resource selector (DMARS) are set for the target transfer conditions, the DMAC transfers data according to the following procedure:

1. Checks to see if transfer is enabled (DE = 1, DME = 1, TEMASK = 0 or 1 (TE = 0 when TEMASK = 0), AE = 0, NMIF = 0).
2. When a transfer request comes and transfer is enabled, the DMAC transfers one transfer unit of data (depending on the settings of the TS1 and TS0 bits). For an auto request, the transfer begins automatically when the DE bit and DME bit are set to 1. The DMATCR value will be decremented by 1 for each transfer. The actual transfer flows vary by address mode and bus mode.
3. When half of the specified transfer count is exceeded (when DMATCR reaches half of the initial value), an HEI interrupt is sent to the CPU if the HIE bit in CHCR is set to 1.
4. When transfer has been completed for the specified count (when DMATCR reaches 0) while the TEMASK bit is 0, the transfer ends normally. If the IE bit in CHCR is set to 1 at this time, a DEI interrupt is sent to the CPU. When DMATCR reaches 0 while the TEMASK bit is 1, the TE bit is set to 1 and then the values set in RSAR, RDAR and RDMATCR are reloaded in SAR, DAR and DMATCR, respectively to continue transfer operation until the DMA transfer request is cancelled.
5. When an address error in the DMAC or an NMI interrupt is generated, the transfer is terminated. Transfers are also terminated when the DE bit in CHCR or the DME bit in DMAOR is cleared to 0.

Figure 10.2 is a flowchart of this procedure.

**Figure 10.2 DMA Transfer Flowchart**

## 10.4.2 DMA Transfer Requests

DMA transfer requests are basically generated in either the data transfer source or destination, but they can also be generated in external devices and on-chip peripheral modules that are neither the transfer source nor destination.

Transfers can be requested in three modes: auto request, external request, and on-chip peripheral module request. The request mode is selected by the RS[3:0] bits in CHCR\_0 to CHCR\_7 and DMARS0 to DMARS3.

### (1) Auto-Request Mode

When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, the auto-request mode allows the DMAC to automatically generate a transfer request signal internally. When the DE bits in CHCR\_0 to CHCR\_7 and the DME bit in DMAOR are set to 1, the transfer begins so long as the TE bits in CHCR\_0 to CHCR\_7, and the AE and NMIF bits in DMAOR are 0.

### (2) External Request Mode

In this mode a transfer is performed at the request signals (DREQ0 to DREQ3) of an external device. Choose one of the modes shown in table 10.5 according to the application system. When the DMA transfer is enabled (DE = 1, DME = 1, TEMASK = 0 or 1 (TE = 0 when TEMASK = 0), AE = 0, NMIF = 0 for level detection; DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0 for edge detection), DMA transfer is performed upon a request at the DREQ input.

**Table 10.5 Selecting External Request Modes with the RS Bits**

| RS[3] | RS[2] | RS[1] | RS[0] | Address Mode        | Transfer Source                                | Transfer Destination                           |
|-------|-------|-------|-------|---------------------|------------------------------------------------|------------------------------------------------|
| 0     | 0     | 0     | 0     | Dual address mode   | Any                                            | Any                                            |
| 0     | 0     | 1     | 0     | Single address mode | External memory, memory-mapped external device | External device with DACK                      |
|       |       |       | 1     |                     | External device with DACK                      | External memory, memory-mapped external device |

Choose to detect DREQ by either the edge or level of the signal input with the DL and DS bits in CHCR\_0 to CHCR\_3 as shown in table 10.6. The source of the transfer request does not have to be the data transfer source or destination. When DREQ is detected by a rising/falling edge and DMA transfer is performed in burst mode, the transfer continues until DMATCR reaches 0 by one DMA transfer request. In cycle steal mode, one DMA transfer is performed by one request.

**Table 10.6 Selecting External Request Detection with DL and DS Bits**

| CHCR   |        |                               |
|--------|--------|-------------------------------|
| DL Bit | DS Bit | Detection of External Request |
| 0      | 0      | Low-level detection           |
|        | 1      | Falling-edge detection        |
| 1      | 0      | High-level detection          |
|        | 1      | Rising-edge detection         |

When DREQ is accepted, the DREQ pin enters the request accept disabled state (non-sensitive period). After issuing acknowledge DACK signal for the accepted DREQ, the DREQ pin again enters the request accept enabled state.

When DREQ is used by level detection, there are following two cases by the timing to detect the next DREQ after outputting DACK.

Overrun 0: Transfer is terminated after the same number of transfer has been performed as requests.

Overrun 1: Transfer is terminated after transfers have been performed for (the number of requests plus 1) times.

The DO bit in CHCR selects this overrun 0 or overrun 1.

**Table 10.7 Selecting External Request Detection with DO Bit**

| CHCR   |                  |
|--------|------------------|
| DO Bit | External Request |
| 0      | Overrun 0        |
| 1      | Overrun 1        |

### (3) On-Chip Peripheral Module Request

In this mode, the transfer is performed in response to the DMA transfer request signal from an on-chip peripheral module.

Table 10.8 lists the DMA transfer request signals sent from on-chip peripheral modules to DMAC.

If DMA transfer is enabled (DE = 1, DME = 1, TEMASK = 0 or 1 (TE = 0 when TEMASK = 0), AE = 0, and NMIF = 0) in on-chip peripheral module request mode, DMA transfer is started by a transfer request signal.

In on-chip peripheral module request mode, there are cases where transfer source or destination is fixed. For details, see table 10.8.

**Table 10.8 Selecting On-Chip Peripheral Module Request Modes with RS3 to RS0 Bits**

| CHCR    | DMARS  |     | DMA Transfer Request | DMA Transfer Request Signal        | Transfer Source | Transfer Destination | Bus Mode             |
|---------|--------|-----|----------------------|------------------------------------|-----------------|----------------------|----------------------|
| RS[3:0] | MID    | RID | Source               |                                    |                 |                      |                      |

|                 | 111111 | 11  | CMT_1                                | CMI1 (compare match)                | Any                | Any                     |                      |

### 10.4.3 Channel Priority

When the DMAC receives simultaneous transfer requests on two or more channels, it selects a channel according to a predetermined priority order. Three modes (fixed mode 1, fixed mode 2, and round-robin mode) are selected using the PR1 and PR0 bits in DMAOR.

#### (1) Fixed Mode

In fixed modes, the priority levels among the channels remain fixed. There are two kinds of fixed modes as follows:

Fixed mode 1: CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7

Fixed mode 2: CH0 > CH4 > CH1 > CH5 > CH2 > CH6 > CH3 > CH7

These are selected by the PR1 and PR0 bits in the DMA operation register (DMAOR).

#### (2) Round-Robin Mode

Each time one unit of word, byte, longword, or 16 bytes is transferred on one channel, the priority order is rotated. The channel on which the transfer was just finished is rotated to the lowest of the priority order among the four round-robin channels (channels 0 to 4). The priority of the channels other than the round-robin channels (channels 0 to 4) does not change even in round-robin mode. The round-robin mode operation is shown in figure 10.3. The priority in round-robin mode is CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7 immediately after a reset.

When the round-robin mode has been specified, do not concurrently specify cycle steal mode and burst mode as the bus modes of any two or more channels.

## (1) When channel 0 transfers

## (2) When channel 1 transfers

## (3) When channel 2 transfers

## (4) When channel 7 transfers

**Figure 10.3 Round-Robin Mode**

Figure 10.4 shows how the priority order changes when channel 0 and channel 3 transfers are requested simultaneously and a channel 1 transfer is requested during the channel 0 transfer. The DMAC operates as follows:

1. Transfer requests are generated simultaneously to channels 0 and 3.
2. Channel 0 has a higher priority, so the channel 0 transfer begins first (channel 3 waits for transfer).
3. A channel 1 transfer request occurs during the channel 0 transfer (channels 1 and 3 are both waiting)
4. When the channel 0 transfer ends, channel 0 is given the lowest priority among the round-robin channels.
5. At this point, channel 1 has a higher priority than channel 3, so the channel 1 transfer begins (channel 3 waits for transfer).
6. When the channel 1 transfer ends, channel 1 is given the lowest priority among the round-robin channels.
7. The channel 3 transfer begins.
8. When the channel 3 transfer ends, channels 3 and 2 are lowered in priority so that channel 3 is given the lowest priority among the round-robin channels.

**Figure 10.4 Changes in Channel Priority in Round-Robin Mode**

#### 10.4.4 DMA Transfer Types

DMA transfer has two types; single address mode transfer and dual address mode transfer. They depend on the number of bus cycles of access to the transfer source and destination. A data transfer timing depends on the bus mode, which is the cycle steal mode or burst mode. The DMAC supports the transfers shown in table 10.9.

**Table 10.9 Supported DMA Transfers**

| Transfer Source               | Transfer Destination      |                 |                               |                           |                |
|-------------------------------|---------------------------|-----------------|-------------------------------|---------------------------|----------------|
|                               | External Device with DACK | External Memory | Memory-Mapped External Device | On-Chip Peripheral Module | On-Chip Memory |
| External device with DACK     | Not available             | Dual, single    | Dual, single                  | Dual                      | Dual           |
| External memory               | Dual, single              | Dual            | Dual                          | Dual                      | Dual           |
| Memory-mapped external device | Dual, single              | Dual            | Dual                          | Dual                      | Dual           |
| On-chip peripheral module     | Dual                      | Dual            | Dual                          | Dual                      | Dual           |
| On-chip memory                | Dual                      | Dual            | Dual                          | Dual                      | Dual           |

Notes: 1. Dual: Dual address mode  
 2. Single: Single address mode  
 3. 16-byte transfer is available only for on-chip peripheral modules that support longword access.

## (1) Address Modes

### (a) Dual Address Mode

In dual address mode, both the transfer source and destination are accessed (selected) by an address. The transfer source and destination can be located externally or internally.

DMA transfer requires two bus cycles because data is read from the transfer source in a data read cycle and written to the transfer destination in a data write cycle. At this time, transfer data is temporarily stored in the DMAC. In the transfer between external memories as shown in figure 10.5, data is read to the DMAC from one external memory in a data read cycle, and then that data is written to the other external memory in a data write cycle.

**Figure 10.5 Data Flow of Dual Address Mode**

Auto request, external request, and on-chip peripheral module request are available for the transfer request. DACK can be output in read cycle or write cycle in dual address mode. The AM bit in the channel control register (CHCR) can specify whether the DACK is output in read cycle or write cycle.

Figure 10.6 shows an example of DMA transfer timing in dual address mode.

**Figure 10.6 Example of DMA Transfer Timing in Dual Mode**  
**(Transfer Source: Normal Memory, Transfer Destination: Normal Memory)**

### (b) Single Address Mode

In single address mode, both the transfer source and destination are external devices, either of them is accessed (selected) by the DACK signal, and the other device is accessed by an address. In this mode, the DMAC performs one DMA transfer in one bus cycle, accessing one of the external devices by outputting the DACK transfer request acknowledge signal to it, and at the same time outputting an address to the other device involved in the transfer. For example, in the case of transfer between external memory and an external device with DACK shown in figure 10.7, when the external device outputs data to the data bus, that data is written to the external memory in the same bus cycle.

**Figure 10.7 Data Flow in Single Address Mode**

Two kinds of transfer are possible in single address mode: (1) transfer between an external device with DACK and a memory-mapped external device, and (2) transfer between an external device with DACK and external memory. In both cases, only the external request signal (DREQ) is used for transfer requests.

Figure 10.8 shows an example of DMA transfer timing in single address mode.

**Figure 10.8 Example of DMA Transfer Timing in Single Address Mode**

## (2) Bus Modes

There are two bus modes; cycle steal and burst. Select the mode by the TB bits in the channel control registers (CHCR).

### (a) Cycle Steal Mode

#### • Normal mode

In normal mode of cycle steal, the bus mastership is given to another bus master after a one-transfer-unit (byte, word, longword, or 16-byte unit) DMA transfer. When another transfer request occurs, the bus mastership is obtained from another bus master and a transfer is performed for one transfer unit. When that transfer ends, the bus mastership is passed to another bus master. This is repeated until the transfer end conditions are satisfied.

The cycle-steal normal mode can be used for any transfer section; transfer request source, transfer source, and transfer destination.

Figure 10.9 shows an example of DMA transfer timing in cycle-steal normal mode. Transfer conditions shown in the figure are;

- Dual address mode
- DREQ low level detection

**Figure 10.9 DMA Transfer Example in Cycle-Steal Normal Mode  
(Dual Address, DREQ Low Level Detection)**

- Intermittent Mode 16 and Intermittent Mode 64

In intermittent mode of cycle steal, DMAC returns the bus mastership to other bus master whenever a unit of transfer (byte, word, longword, or 16 bytes) is completed. If the next transfer request occurs after that, DMAC obtains the bus mastership from other bus master after waiting for 16 or 64 cycles of  $B\phi$  clock. DMAC then transfers data of one unit and returns the bus mastership to other bus master. These operations are repeated until the transfer end condition is satisfied. It is thus possible to make lower the ratio of bus occupation by DMA transfer than the normal mode of cycle steal.

When DMAC obtains again the bus mastership, DMA transfer may be postponed in case of entry updating due to cache miss.

The cycle-steal intermittent mode can be used for any transfer section; transfer request source, transfer source, and transfer destination. The bus modes, however, must be cycle steal mode in all channels.

Figure 10.10 shows an example of DMA transfer timing in cycle-steal intermittent mode. Transfer conditions shown in the figure are;

- Dual address mode
- DREQ low level detection

**Figure 10.10 Example of DMA Transfer in Cycle-Steal Intermittent Mode  
(Dual Address, DREQ Low Level Detection)**

(b) Burst Mode

In burst mode, once the DMAC obtains the bus mastership, it does not release the bus mastership and continues to perform transfer until the transfer end condition is satisfied. In external request mode with low level detection of the DREQ pin, however, when the DREQ pin is driven high, the bus mastership is passed to another bus master after the DMAC transfer request that has already been accepted ends, even if the transfer end conditions have not been satisfied.

Figure 10.11 shows DMA transfer timing in burst mode.

Figure 10.11 DMA Transfer Example in Burst Mode  
(Dual Address, DREQ Low Level Detection)

(3) Relationship between Request Modes and Bus Modes by DMA Transfer Category

Table 10.10 shows the relationship between request modes and bus modes by DMA transfer category.

Table 10.10 Relationship of Request Modes and Bus Modes by DMA Transfer Category

| Address Mode | Transfer Category                                               | Request Mode      | Bus Mode          | Transfer Size (Bits)      | Usable Channels      |
|--------------|-----------------------------------------------------------------|-------------------|-------------------|---------------------------|----------------------|
| Dual         | External device with DACK and external memory                   | External          | B/C               | 8/16/32/128               | 0 to 3               |
|              | External device with DACK and memory-mapped external device     | External          | B/C               | 8/16/32/128               | 0 to 3               |
|              | External device with DACK and on-chip peripheral module         | External          | B/C               | 8/16/32/128* <sup>2</sup> | 0 to 3               |
|              | External device with DACK and on-chip memory                    | External          | B/C               | 8/16/32/128               | 0 to 3               |
|              | External memory and external memory                             | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | External memory and memory-mapped external device               | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | Memory-mapped external device and memory-mapped external device | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | External memory and on-chip peripheral module                   | All* <sup>1</sup> | B/C* <sup>5</sup> | 8/16/32/128* <sup>2</sup> | 0 to 7* <sup>3</sup> |

| Address Mode | Transfer Category                                           | Request Mode      | Bus Mode          | Transfer Size (Bits)      | Usable Channels      |
|--------------|-------------------------------------------------------------|-------------------|-------------------|---------------------------|----------------------|
| Dual         | Memory-mapped external device and on-chip peripheral module | All* <sup>1</sup> | B/C* <sup>5</sup> | 8/16/32/128* <sup>2</sup> | 0 to 7* <sup>3</sup> |
|              | On-chip peripheral module and on-chip peripheral module     | All* <sup>1</sup> | B/C* <sup>5</sup> | 8/16/32/128* <sup>2</sup> | 0 to 7* <sup>3</sup> |
|              | On-chip memory and on-chip memory                           | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | On-chip memory and memory-mapped external device            | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | On-chip memory and on-chip peripheral module                | All* <sup>1</sup> | B/C* <sup>5</sup> | 8/16/32/128* <sup>2</sup> | 0 to 7* <sup>3</sup> |
|              | On-chip memory and external memory                          | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
| Single       | External device with DACK and external memory               | External          | B/C               | 8/16/32/128               | 0 to 3               |
|              | External device with DACK and memory-mapped external device | External          | B/C               | 8/16/32/128               | 0 to 3               |

## [Legend]

B: Burst

C: Cycle steal

- Notes:
1. External requests, auto requests, and on-chip peripheral module requests are all available. However, in the case of internal module request, along with the exception of MTU2 and CMT as the transfer request source, the requesting module must be designated as the transfer source or the transfer destination.
  2. Access size permitted for the on-chip peripheral module register functioning as the transfer source or transfer destination.
  3. If the transfer request is an external request, channels 0 to 3 are only available.
  4. External requests, auto requests, and on-chip peripheral module requests are all available. In the case of on-chip peripheral module requests, however, the CMT and MTU2 are only available.
  5. In the case of on-chip peripheral module request, only cycle steal except for the USB, SSI, MTU2, and CMT as the transfer request source.

#### (4) Bus Mode and Channel Priority

In priority fixed mode ( $CH0 > CH1$ ), when channel 1 is transferring data in burst mode and a request arrives for transfer on channel 0, which has higher-priority, the data transfer on channel 0 will begin immediately. In this case, if the transfer on channel 0 is also in burst mode, the transfer on channel 1 will only resume on completion of the transfer on channel 0.

When channel 0 is in cycle steal mode, one transfer-unit of data on this channel, which has the higher priority, is transferred. Data is then transferred continuously to channel 1 without releasing the bus. The bus mastership will then switch between the two in this order: channel 0, channel 1, channel 0, channel 1, etc. That is, the CPU cycle after the data transfer in cycle steal mode is replaced with a burst-mode transfer cycle (priority execution of burst-mode cycle). An example of this is shown in figure 10.12.

When multiple channels are in burst mode, data transfer on the channel that has the highest priority is given precedence. When DMA transfer is being performed on multiple channels, the bus mastership is not released to another bus-master device until all of the competing burst-mode transfers have been completed.

**Figure 10.12 Bus State when Multiple Channels are Operating**

In round-robin mode, the priority changes as shown in figure 10.3. Note that channels in cycle steal and burst modes must not be mixed.

### 10.4.5 Number of Bus Cycles and DREQ Pin Sampling Timing

#### (1) Number of Bus Cycles

When the DMAC is the bus master, the number of bus cycles is controlled by the bus state controller (BSC) in the same way as when the CPU is the bus master. For details, see section 9, Bus State Controller (BSC).

#### (2) DREQ Pin Sampling Timing

Figures 10.13 to 10.16 show the DREQ input sampling timings in each bus mode.

**Figure 10.13 Example of DREQ Input Detection in Cycle Steal Mode Edge Detection**

**Figure 10.14 Example of DREQ Input Detection in Cycle Steal Mode Level Detection**

**Figure 10.15 Example of DREQ Input Detection in Burst Mode Edge Detection**

**Figure 10.16 Example of DREQ Input Detection in Burst Mode Level Detection**

Figure 10.17 shows the TEND output timing.

**Figure 10.17 Example of DMA Transfer End Signal Timing  
(Cycle Steal Mode Level Detection)**

The unit of the DMA transfer is divided into multiple bus cycles when 16-byte transfer is performed for an 8-bit, 16-bit, or 32-bit external device, when longword access is performed for an 8-bit or 16-bit external device, or when word access is performed for an 8-bit external device. When a setting is made so that the DMA transfer size is divided into multiple bus cycles and the  $\overline{CS}$  signal is negated between bus cycles, note that DACK and TEND are divided like the  $\overline{CS}$  signal for data alignment as shown in figure 10.18. Figures 10.13 to 10.17 show the cases where DACK and TEND are not divided in the DMA transfer.

Note: TEND is asserted for the last unit of DMA transfer. If a transfer unit is divided into multiple bus cycles and the CS is negated between the bus cycles, TEND is also divided.

**Figure 10.18 BSC Normal Memory Access**  
**(No Wait, Idle Cycle 1, Longword Access to 16-Bit Device)**

## 10.5 Usage Notes

### 10.5.1 Setting of the Half-End Flag and Generation of the Half-End Interrupt

When executing DMA transfer by reload function of DMAC, setting different value to DMA reload transfer count register (RDMATCR\_n) from the DMA transfer count register (DMATCR\_n) value set when transfer is started lead to an error in the operation of the half end flag of DMA channel control register (CHCR\_n). Even though the value of DMATCR\_n is rewritten by reload operation, half end flag is set based on the value set when transfer is started. Because of this, there may be errors where (a) the set timing of the half end flag is not correct, or (b) the half end flag can not be set, may be generated. When executing DMA transfer by reload function under the condition that different values are set to RDMATCR\_n from DMATCR\_n, do not use half end flag or half end interrupt.

### 10.5.2 Timing of DACK and TEND Outputs

When the external memory is the MPX-I/O or burst MPX-I/O, the DACK output is asserted with the timing of the data cycle. For details, see the respective figures in section 9.5.5, MPX-I/O Interface, or section 9.5.10, Burst MPX-I/O Interface.

When the memory is other than the MPX-I/O or burst MPX-I/O, the DACK output is asserted with the same timing as the corresponding CS signal.

The TEND output does not depend on the type of memory and is always asserted with the same timing as the corresponding CS signal.

### 10.5.3 Notice about using external request mode

In case that one or more channels are set that transfer request source is external request signal DREQ, please use one of the following four ways.

- 1) Please set all channels to cycle-steal mode.
- 2) Please set all channels to burst-mode with all of the following three conditions.
  - 2-1) Please set channel priority mode to fixed mode 1 or fixed mode 2.
  - 2-2) Please set all channels to dual-address mode.
  - 2-3) Please set transfer source address and transfer destination address of each channels to one of the followings.
    - A. transfer source address: external address space  
transfer destination address: external address space
    - B. transfer source address: external address space  
transfer destination address: internal address space
    - C. transfer source address: internal address space  
transfer destination address: internal address space
- 3) If there are both of one or more channels set to cycle-steal mode and one or more channels set to burst mode, please use with all of the following three conditions.
  - 3-1) Please set channel priority mode to fixed mode 1 or fixed mode 2.
  - 3-2) Please set all channels to dual-address mode.
  - 3-3) Please set transfer source address and transfer destination address of each channels to one of the followings.
    - A. transfer source address: external address space  
transfer destination address: external address space
    - B. transfer source address: external address space  
transfer destination address: internal address space
    - C. transfer source address: internal address space  
transfer destination address: internal address space
- 4) Please use only one channel.

If using other than the above four ways, there is a possibility that DACK<sub>n</sub> pin and TEND<sub>n</sub> pin show wrong transfer channel and since then until power-on reset DMA transfer is unavailable. Additionally if this state occurs in burst-mode, CPU becomes unable to fetch instructions, then system becomes suspended.

### 10.5.4 Notice about using on-chip peripheral module request mode or auto-request mode

In case that one or more channels are set that transfer request source is on-chip peripheral module request or auto-request mode and use DACKn pin or TENDn pin, please use one of the following four ways.

- 1) Please set all channels to cycle-steal mode.
- 2) Please set all channels to burst-mode with all of the following three conditions.
  - 2-1) Please set channel priority mode to fixed mode 1 or fixed mode 2.
  - 2-2) Please set all channels to dual-address mode.
  - 2-3) Please set transfer source address and transfer destination address of each channels to one of the followings.
    - A. transfer source address: external address space  
transfer destination address: external address space
    - B. transfer source address: external address space  
transfer destination address: internal address space
    - C. transfer source address: internal address space  
transfer destination address: internal address space
- 3) If there are both of one or more channels set to cycle-steal mode and one or more channels set to burst mode, please use with all of the following three conditions.
  - 3-1) Please set channel priority mode to fixed mode 1 or fixed mode 2.
  - 3-2) Please set all channels to dual-address mode.
  - 3-3) Please set transfer source address and transfer destination address of each channels to one of the followings.
    - A. transfer source address: external address space  
transfer destination address: external address space
    - B. transfer source address: external address space  
transfer destination address: internal address space
    - C. transfer source address: internal address space  
transfer destination address: internal address space
- 4) Please use only one channel.

If using other than the above four ways, there is a possibility that DACKn pin and TENDn pin show wrong transfer channel.

### 10.5.5 Notes on Using Flag Bits

The notes on using the following flag bits are described here.

- DMA channel control register (CHCR)  
HE (Half-End) and TE (Transfer End Flag) bits
- DMA operation register (DMAOR)  
AE (Address Error Flag) and NMIF (NMI Flag) bits

If a flag is read at the same timing it is set to 1, the read data will be 0, but the internal state may be the same as reading 1. Therefore, if 0 is written to the flag, the flag will be cleared to 0 because the internal state is the same as when writing 0 after reading 1.

In the case of using a flag, to prevent from unintentionally clearing the flag bit to 0, perform read/write as follows:

- (a) In the case of intended bit clear, write 0 to the flag bit after reading it as 1.
- (b) In other cases, write 1 to the flag bit.

If a flag is not used, just writing 0 to the flag bit does not generate errors (in the case of intended bit clear, write 0 to the flag bit after reading it as 1).

## Section 11 Multi-Function Timer Pulse Unit 2 (MTU2)

This LSI has an on-chip multi-function timer pulse unit 2 (MTU2) that comprises five 16-bit timer channels.

### 11.1 Features

- Maximum 16 pulse input/output lines
- Selection of eight counter input clocks for each channel
- The following operations can be set:
  - Waveform output at compare match
  - Input capture function
  - Counter clear operation
  - Multiple timer counters (TCNT) can be written to simultaneously
  - Simultaneous clearing by compare match and input capture is possible
  - Register simultaneous input/output is possible by synchronous counter operation
  - A maximum 12-phase PWM output is possible in combination with synchronous operation
- Buffer operation settable for channels 0, 3, and 4
- Phase counting mode settable independently for each of channels 1 and 2
- Cascade connection operation
- Fast access via internal 16-bit bus
- 28 interrupt sources
- Automatic transfer of register data
- A/D converter start trigger can be generated
- Module standby mode can be settable
- A total of six-phase waveform output, which includes complementary PWM output, and positive and negative phases of reset PWM output by interlocking operation of channels 3 and 4, is possible.
- AC synchronous motor (brushless DC motor) drive mode using complementary PWM output and reset PWM output is settable by interlocking operation of channels 0, 3, and 4, and the selection of two types of waveform outputs (chopping and level) is possible.
- In complementary PWM mode, interrupts at the crest and trough of the counter value and A/D converter start triggers can be skipped.

**Table 11.1 MTU2 Functions**

| Item                                   | Channel 0                                                                                      | Channel 1                                                                                     | Channel 2                                                                                               | Channel 3                                                                                                       | Channel 4                                                                                                       |

The diagram illustrates the internal architecture of the TMR module. It is divided into two main sections: **Control logic for channels 3 and 4** (top) and **Control logic for channels 0 to 2** (bottom). Each section contains four channels (Channel 3, Channel 4, Channel 2, Channel 1, and Channel 0) and a **Common Control logic** block. The channels are connected to a **Module data bus**, which in turn connects to a **BUS I/F** block. The **BUS I/F** block is connected to a **Peripheral bus** and an **A/D converter conversion start signal**. The **Common Control logic** block is connected to a **Clock input** and an **External clock** input. The **Peripheral bus** is connected to **Interrupt request signals** for each channel. The **A/D converter conversion start signal** is connected to the **Peripheral bus**.

**Input/output pins**

Channel 3: TIOC3A, TIOC3B, TIOC3C, TIOC3D  
Channel 4: TIOC4A, TIOC4B, TIOC4C, TIOC4D

**Clock input**

Internal clock: P<sub>6</sub>/1, P<sub>6</sub>/4, P<sub>6</sub>/16, P<sub>6</sub>/64, P<sub>6</sub>/256, P<sub>6</sub>/1024  
External clock: TCLKA, TCLKB, TCLKC, TCLKD

**Interrupt request signals**

Channel 3: TGIA\_3, TGB\_3, TGIC\_3, TGID\_3, TCIV\_3  
Channel 4: TGIA\_4, TGB\_4, TGIC\_4, TGID\_4, TCIV\_4

**Peripheral bus**

**A/D converter conversion start signal**

**Interrupt request signals**

Channel 0: TGIA\_0, TGB\_0, TGIC\_0, TGID\_0, TGIE\_0, TGIF\_0, TCIV\_0  
Channel 1: TGIA\_1, TGB\_1, TGIC\_1, TGID\_1, TCIV\_1  
Channel 2: TGIA\_2, TGB\_2, TGIC\_2, TGID\_2, TCIV\_2

|         | TIOC3C   | I/O   | TGRC_3 input capture input/output compare output/PWM output pin             |
|         | TIOC3D   | I/O   | TGRD_3 input capture input/output compare output/PWM output pin             |
| 4       | TIOC4A   | I/O   | TGRA_4 input capture input/output compare output/PWM output pin             |
|         | TIOC4B   | I/O   | TGRB_4 input capture input/output compare output/PWM output pin             |
|         | TIOC4C   | I/O   | TGRC_4 input capture input/output compare output/PWM output pin             |
|         | TIOC4D   | I/O   | TGRD_4 input capture input/output compare output/PWM output pin             |

Note: For the pin configuration in complementary PWM mode, see table 11.52.

## 11.3 Register Descriptions

The MTU2 has the following registers. For details on register addresses and register states during each process, refer to section 30, List of Registers. To distinguish registers in each channel, an underscore and the channel number are added as a suffix to the register name; TCR for channel 0 is expressed as TCR\_0.

**Table 11.3 Register Descriptions**

| Channel | Register Name                                   | Abbreviation | R/W | Initial Value | Address    | Access Size |
|---------|-------------------------------------------------|--------------|-----|---------------|------------|-------------|
| 0       | Timer control register_0                        | TCR_0        | R/W | H'00          | H'FFFE4300 | 8           |
|         | Timer mode register_0                           | TMDR_0       | R/W | H'00          | H'FFFE4301 | 8           |
|         | Timer I/O control register H_0                  | TIORH_0      | R/W | H'00          | H'FFFE4302 | 8           |

### 11.3.1 Timer Control Register (TCR)

The TCR registers are 8-bit readable/writable registers that control the TCNT operation for each channel. The MTU2 has a total of five TCR registers, one each for channels 0 to 4. TCR register settings should be conducted only when TCNT operation is stopped.

| Bit    | Bit Name  | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

See tables 11.4 and 11.5 for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 4, 3   | CKEG[1:0] | 00            | R/W | Clock Edge 0 and 1<br>These bits select the input clock edge. When the input clock is counted using both edges, the input clock period is halved (e.g. $P\phi/4$ both edges = $P\phi/2$ rising edge). If phase counting mode is used on channels 1 and 2, this setting is ignored and the phase counting mode setting has priority. Internal clock edge selection is valid when the input clock is $P\phi/4$ or slower. When $P\phi/1$ , or the overflow/underflow of another channel is selected for the input clock, although values can be written, counter operation compiles with the initial value.<br>00: Count at rising edge<br>01: Count at falling edge<br>1x: Count at both edges |
| 2 to 0 | TPSC[2:0] | 000           | R/W | Time Prescaler 0 to 2<br>These bits select the TCNT counter clock. The clock source can be selected independently for each channel. See tables 11.6 to 11.9 for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 11.4 CCLR0 to CCLR2 (Channels 0, 3, and 4)**

| Channel | Bit 7<br>CCLR2 | Bit 6<br>CCLR1 | Bit 5<br>CCLR0 | Description                                                                                                              |
|---------|----------------|----------------|----------------|--------------------------------------------------------------------------------------------------------------------------|
| 0, 3, 4 | 0              | 0              | 0              | TCNT clearing disabled                                                                                                   |
|         |                |                | 1              | TCNT cleared by TGRA compare match/input capture                                                                         |
|         |                | 1              | 0              | TCNT cleared by TGRB compare match/input capture                                                                         |
|         |                |                | 1              | TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup> |
|         | 1              | 0              | 0              | TCNT clearing disabled                                                                                                   |
|         |                |                | 1              | TCNT cleared by TGRC compare match/input capture* <sup>2</sup>                                                           |
|         |                | 1              | 0              | TCNT cleared by TGRD compare match/input capture* <sup>2</sup>                                                           |
|         |                |                | 1              | TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup> |

Notes: 1. Synchronous operation is set by setting the SYNC bit in TSYR to 1.

2. When TGRC or TGRD is used as a buffer register, TCNT is not cleared because the buffer register setting has priority, and compare match/input capture does not occur.

**Table 11.5 CCLR0 to CCLR2 (Channels 1 and 2)**

| Channel | Bit 7<br>Reserved* <sup>2</sup> | Bit 6<br>CCLR1 | Bit 5<br>CCLR0 | Description                                                                                                              |
|---------|---------------------------------|----------------|----------------|--------------------------------------------------------------------------------------------------------------------------|
| 1, 2    | 0                               | 0              | 0              | TCNT clearing disabled                                                                                                   |
|         |                                 |                | 1              | TCNT cleared by TGRA compare match/input capture                                                                         |
|         |                                 | 1              | 0              | TCNT cleared by TGRB compare match/input capture                                                                         |
|         |                                 |                | 1              | TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup> |

Notes: 1. Synchronous operation is selected by setting the SYNC bit in TSYR to 1.

2. Bit 7 is reserved in channels 1 and 2. It is always read as 0 and cannot be modified.

**Table 11.6 TPSC0 to TPSC2 (Channel 0)**

| Channel | Bit 2<br>TPSC2 | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                               |
|---------|----------------|----------------|----------------|-------------------------------------------|
| 0       | 0              | 0              | 0              | Internal clock: counts on P $\phi$ /1     |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /4     |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /16    |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /64    |
|         | 1              | 0              | 0              | External clock: counts on TCLKA pin input |
|         |                |                | 1              | External clock: counts on TCLKB pin input |
|         |                | 1              | 0              | External clock: counts on TCLKC pin input |
|         |                |                | 1              | External clock: counts on TCLKD pin input |

**Table 11.7 TPSC0 to TPSC2 (Channel 1)**

| Channel | Bit 2<br>TPSC2 | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                               |
|---------|----------------|----------------|----------------|-------------------------------------------|
| 1       | 0              | 0              | 0              | Internal clock: counts on P $\phi$ /1     |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /4     |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /16    |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /64    |
|         | 1              | 0              | 0              | External clock: counts on TCLKA pin input |
|         |                |                | 1              | External clock: counts on TCLKB pin input |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /256   |
|         |                |                | 1              | Counts on TCNT_2 overflow/underflow       |

Note: This setting is ignored when channel 1 is in phase counting mode.

**Table 11.8 TPSC0 to TPSC2 (Channel 2)**

| Channel | Bit 2<br>TPSC2 | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                               |
|---------|----------------|----------------|----------------|-------------------------------------------|
| 2       | 0              | 0              | 0              | Internal clock: counts on P $\phi$ /1     |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /4     |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /16    |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /64    |
|         | 1              | 0              | 0              | External clock: counts on TCLKA pin input |
|         |                |                | 1              | External clock: counts on TCLKB pin input |
|         |                | 1              | 0              | External clock: counts on TCLKC pin input |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /1024  |

Note: This setting is ignored when channel 2 is in phase counting mode.

**Table 11.9 TPSC0 to TPSC2 (Channels 3 and 4)**

| Channel | Bit 2<br>TPSC2 | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                               |
|---------|----------------|----------------|----------------|-------------------------------------------|
| 3, 4    | 0              | 0              | 0              | Internal clock: counts on P $\phi$ /1     |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /4     |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /16    |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /64    |
|         | 1              | 0              | 0              | Internal clock: counts on P $\phi$ /256   |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /1024  |
|         |                | 1              | 0              | External clock: counts on TCLKA pin input |
|         |                |                | 1              | External clock: counts on TCLKB pin input |

11.3.2 Timer Mode Register (TMDR)

The TMDR registers are 8-bit readable/writable registers that are used to set the operating mode of each channel. The MTU2 has five TMDR registers, one each for channels 0 to 4. TMDR register settings should be changed only when TCNT operation is stopped.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | —        | 0             | R   | Reserved<br><br>This bit is always read as 0. The write value should always be 0.                                                                                                                                                                                                                                                                                                                                                                    |

|              |              | 1            | 0            | Complementary PWM mode 2 (transmit at trough) <sup>*3</sup>           |
|              |              |              | 1            | Complementary PWM mode 3 (transmit at crest and trough) <sup>*3</sup> |

[Legend]

X: Don't care

- Notes:
1. PWM mode 2 cannot be set for channels 3 and 4.
  2. Phase counting mode cannot be set for channels 0, 3, and 4.
  3. Reset synchronous PWM mode, complementary PWM mode can only be set for channel 3. When channel 3 is set to reset synchronous PWM mode or complementary PWM mode, the channel 4 settings become ineffective and automatically conform to the channel 3 settings. However, do not set channel 4 to reset synchronous PWM mode or complementary PWM mode. Reset synchronous PWM mode and complementary PWM mode cannot be set for channels 0, 1, and 2.

### 11.3.3 Timer I/O Control Register (TIOR)

The TIOR registers are 8-bit readable/writable registers that control the TGR registers. The MTU2 has a total of eight TIOR registers, two each for channels 0, 3, and 4, one each for channels 1 and 2.

TIOR should be set while TMDR is set in normal operation, PWM mode, or phase counting mode.

The initial output specified by TIOR is valid when the counter is stopped (the CST bit in TSTR is cleared to 0). Note also that, in PWM mode 2, the output at the point at which the counter is cleared to 0 is specified.

When TGRC or TGRD is designated for buffer operation, this setting is invalid and the register operates as a buffer register.

[Legend]

X: Don't care

- Notes: 1. After power-on reset, 0 is output until TIOR is set.
2. When the BFB bit in TMDR\_0 is set to 1 and TGRD\_0 is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

[Legend]

X: Don't care

- Notes: 1. After power-on reset, 0 is output until TIOR is set.
2. When the BFA bit in TMDR\_0 is set to 1 and TGRC\_0 is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

[Legend]

X: Don't care

Notes: 1. After power-on reset, 0 is output until TIOR is set.

2. When the BFA bit in TMDR\_4 is set to 1 and TGRC\_4 is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

### 11.3.4 Timer Interrupt Enable Register (TIER)

The TIER registers are 8-bit readable/writable registers that control enabling or disabling of interrupt requests for each channel. The MTU2 has six TIER registers, two for channel 0 and one each for channels 1 to 4.

### 11.3.5 Timer Status Register (TSR)

The TSR registers are 8-bit readable/writable registers that indicate the status of each channel. The MTU2 has six TSR registers, two for channel 0 and one each for channels 1 to 4.

- TSR\_0, TSR\_1, TSR\_2, TSR\_3, TSR\_4

|-----|----------|---------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | TGFA     | 0             | R/(W)* <sup>1</sup> | <p>Input Capture/Output Compare Flag A</p> <p>Status flag that indicates the occurrence of TGRA input capture or compare match. Only 0 can be written, for flag clearing.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• When DMAC is activated by TGIA interrupt</li> <li>• When 0 is written to TGFA after reading<br/>TGFA = 1*<sup>2</sup></li> </ul> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• When TCNT = TGRA and TGRA is functioning as output compare register</li> <li>• When TCNT value is transferred to TGRA by input capture signal and TGRA is functioning as input capture register</li> </ul> |

Notes: 1. Writing 0 to this bit after reading it as 1 clears the flag and is the only allowed way.

2. If the next flag is set before TGFA is cleared to 0 after reading TGFA = 1, TGFA remains 1 even when 0 is written to. In this case, read TGFA = 1 again to clear TGFA to 0.

- TSR2\_0

| 1      | TGFF     | 0             | R/(W)*1 | Compare Match Flag F<br>Status flag that indicates the occurrence of compare match between TCNT_0 and TGRF_0.<br>[Clearing condition] <ul style="list-style-type: none"> <li>When 0 is written to TGFF after reading<br/>TGFF = 1*2</li> </ul> [Setting condition] <ul style="list-style-type: none"> <li>When TCNT_0 = TGRF_0 and TGRF_0 is functioning as compare register</li> </ul> |
| 0      | TGFE     | 0             | R/(W)*1 | Compare Match Flag E<br>Status flag that indicates the occurrence of compare match between TCNT_0 and TGRE_0.<br>[Clearing condition] <ul style="list-style-type: none"> <li>When 0 is written to TGFE after reading<br/>TGFE = 1*2</li> </ul> [Setting condition] <ul style="list-style-type: none"> <li>When TCNT_0 = TGRE_0 and TGRE_0 is functioning as compare register</li> </ul> |

Notes: 1. Writing 0 to this bit after reading it as 1 clears the flag and is the only allowed way.  
2. If the next flag is set before TGFE is cleared to 0 after reading TGFE = 1, TGFE remains 1 even when 0 is written to. In this case, read TGFE = 1 again to clear TGFE to 0.

### 11.3.6 Timer Buffer Operation Transfer Mode Register (TBTM)

The TBTM registers are 8-bit readable/writable registers that specify the timing for transferring data from the buffer register to the timer general register in PWM mode. The MTU2 has three TBTM registers, one each for channels 0, 3, and 4.

### 11.3.7 Timer Input Capture Control Register (TICCR)

TICCR is an 8-bit readable/writable register that specifies input capture conditions when TCNT\_1 and TCNT\_2 are cascaded. The MTU2 has one TICCR in channel 1.

### 11.3.8 Timer A/D Converter Start Request Control Register (TADCR)

TADCR is a 16-bit readable/writable register that enables or disables A/D converter start requests and specifies whether to link A/D converter start requests with interrupt skipping operation. The MTU2 has one TADCR in channel 4.

|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | ITB4VE   | 0*            | R/W | TCIV_4 Interrupt Skipping Link Enable<br>Select whether to link A/D converter start requests (TRG4BN) with TCIV_4 interrupt skipping operation.<br>0: Does not link with TCIV_4 interrupt skipping<br>1: Links with TCIV_4 interrupt skipping |

- Notes:
1. TADCR must not be accessed in eight bits; it should always be accessed in 16 bits.
  2. When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), do not link A/D converter start requests with interrupt skipping operation (clear the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR) to 0).
  3. If link with interrupt skipping is enabled while interrupt skipping is disabled, A/D converter start requests will not be issued.
- \* Do not set to 1 when complementary PWM mode is not selected.

**Table 11.27 Setting of Transfer Timing by Bits BF1 and BF0**

| Bit 7 | Bit 6 | Description                                                                                                                            |
|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------|
| BF1   | BF0   |                                                                                                                                        |
| 0     | 0     | Does not transfer data from the cycle set buffer register to the cycle set register.                                                   |
| 0     | 1     | Transfers data from the cycle set buffer register to the cycle set register at the crest of the TCNT_4 count.* <sup>1</sup>            |
| 1     | 0     | Transfers data from the cycle set buffer register to the cycle set register at the trough of the TCNT_4 count.* <sup>2</sup>           |
| 1     | 1     | Transfers data from the cycle set buffer register to the cycle set register at the crest and trough of the TCNT_4 count.* <sup>2</sup> |

- Notes:
1. Data is transferred from the cycle set buffer register to the cycle set register when the crest of the TCNT\_4 count is reached in complementary PWM mode, when compare match occurs between TCNT\_3 and TGRA\_3 in reset-synchronized PWM mode, or when compare match occurs between TCNT\_4 and TGRA\_4 in PWM mode 1 or normal operation mode.
  2. These settings are prohibited when complementary PWM mode is not selected.

11.3.9 Timer A/D Converter Start Request Cycle Set Registers (TADCORA\_4 and TADCORB\_4)

TADCORA\_4 and TADCORB\_4 are 16-bit readable/writable registers. When the TCNT\_4 count reaches the value in TADCORA\_4 or TADCORB\_4, a corresponding A/D converter start request will be issued.

TADCORA\_4 and TADCORB\_4 are initialized to H'FFFF.

Note: TADCORA\_4 and TADCORB\_4 must not be accessed in eight bits; they should always be accessed in 16 bits.

11.3.10 Timer A/D Converter Start Request Cycle Set Buffer Registers (TADCOBRA\_4 and TADCOBRB\_4)

TADCOBRA\_4 and TADCOBRB\_4 are 16-bit readable/writable registers. When the crest or trough of the TCNT\_4 count is reached, these register values are transferred to TADCORA\_4 and TADCORB\_4, respectively.

TADCOBRA\_4 and TADCOBRB\_4 are initialized to H'FFFF.

Note: TADCOBRA\_4 and TADCOBRB\_4 must not be accessed in eight bits; they should always be accessed in 16 bits.

### 11.3.11 Timer Counter (TCNT)

The TCNT counters are 16-bit readable/writable counters. The MTU2 has five TCNT counters, one each for channels 0 to 4.

The TCNT counters must not be accessed in eight bits; they should always be accessed in 16 bits.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Note: The TCNT counters must not be accessed in eight bits; they should always be accessed in 16 bits.

### 11.3.12 Timer General Register (TGR)

The TGR registers are 16-bit readable/writable registers. The MTU2 has eighteen TGR registers, six for channel 0, two each for channels 1 and 2, four each for channels 3 and 4.

TGRA, TGRB, TGRC, and TGRD function as either output compare or input capture registers. TGRC and TGRD for channels 0, 3, and 4 can also be designated for operation as buffer registers. TGR buffer register combinations are TGRA and TGRC, and TGRB and TGRD.

TGRE\_0 and TGRF\_0 function as compare registers. When the TCNT\_0 count matches the TGRE\_0 value, an A/D converter start request can be issued. TGRF can also be designated for operation as a buffer register. TGR buffer register combination is TGRE and TGRF.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Note: The TGR registers must not be accessed in eight bits; they should always be accessed in 16 bits.  
TGR registers are initialized to H'FFFF.

### 11.3.13 Timer Start Register (TSTR)

TSTR is an 8-bit readable/writable register that selects operation/stoppage of TCNT for channels 0 to 4.

When setting the operating mode in TMDR or setting the count clock in TCR, first stop the TCNT counter.

### 11.3.14 Timer Synchronous Register (TSYR)

TSYR is an 8-bit readable/writable register that selects independent operation or synchronous operation for the channel 0 to 4 TCNT counters. A channel performs synchronous operation when the corresponding bit in TSYR is set to 1.

11.3.15 Timer Read/Write Enable Register (TRWER)

TRWER is an 8-bit readable/writable register that enables or disables access to the registers and counters which have write-protection capability against accidental modification in channels 3 and 4.

22 registers: TCR\_3, TCR\_4, TMDR\_3, TMDR\_4, TIORH\_3, TIORH\_4, TIORL\_3, TIORL\_4, TIER\_3, TIER\_4, TGRA\_3, TGRA\_4, TGRB\_3, TGRB\_4, TOER, TOCR1, TOCR2, TGCR, TCDR, TDDR, TCNT\_3, and TCNT4.

### 11.3.16 Timer Output Master Enable Register (TOER)

TOER is an 8-bit readable/writable register that enables/disables output settings for output pins TIOC4D, TIOC4C, TIOC3D, TIOC4B, TIOC4A, and TIOC3B. These pins do not output correctly if the TOER bits have not been set. Set TOER of CH3 and CH4 prior to setting TIOR of CH3 and CH4. Set TOER when count operation of TCNT channels 3 and 4 is halted.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                |
|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | OE3B     | 0             | R/W | Master Enable TIOC3B<br>This bit enables/disables the TIOC3B pin MTU2 output.<br>0: MTU2 output is disabled (inactive level)*<br>1: MTU2 output is enabled |

Note: \* The inactive level is determined by the settings in timer output control registers 1 and 2 (TOCR1 and TOCR2). For details, refer to section 11.3.17, Timer Output Control Register 1 (TOCR1), and section 11.3.18, Timer Output Control Register 2 (TOCR2). Set these bits to 1 to enable MTU2 output in other than complementary PWM or reset-synchronized PWM mode. When these bits are set to 0, low level is output.

### 11.3.17 Timer Output Control Register 1 (TOCR1)

TOCR1 is an 8-bit readable/writable register that enables/disables PWM synchronized toggle output in complementary PWM mode/reset synchronized PWM mode, and controls output level inversion of PWM output.

|                |   |      |   |   |        |      |      |      |
|----------------|---|------|---|---|--------|------|------|------|
| Bit:           | 7 | 6    | 5 | 4 | 3      | 2    | 1    | 0    |
|                | - | PSYE | - | - | TOCL   | TOCS | OLSN | OLSP |
| Initial value: | 0 | 0    | 0 | 0 | 0      | 0    | 0    | 0    |
| R/W:           | R | R/W  | R | R | R/(W)* | R/W  | R/W  | R/W  |

Note: \* This bit can be set to 1 only once after a power-on reset. After 1 is written, 0 cannot be written to the bit.

See table 11.29.</p>                                                                                                                      |

- Notes:
1. Setting the TOCL bit to 1 prevents accidental modification when the CPU goes out of control.
  2. Clearing the TOCS0 bit to 0 makes this bit setting valid.
  3. After power-on reset, 1 can be written only once. After 1 has been written, 0 cannot be written.
  4. If there is no dead time, the reverse phase output is the inversion of the forward phase. Set OLSP and OLSN to the same value.

**Table 11.28 Output Level Select Function**

| Bit 1 |                | Function             |            |            |
|-------|----------------|----------------------|------------|------------|
|       |                | Compare Match Output |            |            |
| OLSN  | Initial Output | Active Level         | Up Count   | Down Count |
| 0     | High level     | Low level            | High level | Low level  |
| 1     | Low level      | High level           | Low level  | High level |

Note: The reverse phase waveform initial output value changes to active level after elapse of the dead time after count start.

**Table 11.29 Output Level Select Function**

| Bit 0 |                | Function             |            |            |
|-------|----------------|----------------------|------------|------------|
|       |                | Compare Match Output |            |            |
| OLSP  | Initial Output | Active Level         | Up Count   | Down Count |
| 0     | High level     | Low level            | Low level  | High level |
| 1     | Low level      | High level           | High level | Low level  |

Figure 11.2 shows an example of complementary PWM mode output (1 phase) when OLSN = 1, OLSP = 1.

**Figure 11.2 Complementary PWM Mode Output Level Example**

### 11.3.18 Timer Output Control Register 2 (TOCR2)

TOCR2 is an 8-bit readable/writable register that controls output level inversion of PWM output in complementary PWM mode and reset-synchronized PWM mode.

|                |         |     |       |       |       |       |       |       |

| 0     | High level     | Low level    | Low level            | High level |
| 1     | Low level      | High level   | High level           | Low level  |

**11.3.19 Timer Output Level Buffer Register (TOLBR)**

TOLBR is an 8-bit readable/writable register that functions as a buffer for TOCR2 and specifies the PWM output level in complementary PWM mode and reset-synchronized PWM mode.

|                |   |   |       |       |       |       |       |       |
|----------------|---|---|-------|-------|-------|-------|-------|-------|
| Bit:           | 7 | 6 | 5     | 4     | 3     | 2     | 1     | 0     |
|                | - | - | OLS3N | OLS3P | OLS2N | OLS2P | OLS1N | OLS1P |
| Initial value: | 0 | 0 | 0     | 0     | 0     | 0     | 0     | 0     |
| R/W:           | R | R | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |

| Bit  | Bit Name | Initial value | R/W | Description                                                                      |
|------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 7, 6 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 5    | OLS3N    | 0             | R/W | Specifies the buffer value to be transferred to the OLS3N bit in TOCR2.          |
| 4    | OLS3P    | 0             | R/W | Specifies the buffer value to be transferred to the OLS3P bit in TOCR2.          |
| 3    | OLS2N    | 0             | R/W | Specifies the buffer value to be transferred to the OLS2N bit in TOCR2.          |

| 1    | OLS1N    | 0             | R/W | Specifies the buffer value to be transferred to the OLS1N bit in TOCR2.          |
| 0    | OLS1P    | 0             | R/W | Specifies the buffer value to be transferred to the OLS1P bit in TOCR2.          |

Figure 11.3 shows an example of the PWM output level setting procedure in buffer operation.

Figure 11.3 PWM Output Level Setting Procedure in Buffer Operation

11.3.20 Timer Gate Control Register (TGCR)

TGCR is an 8-bit readable/writable register that controls the waveform output necessary for brushless DC motor control in reset-synchronized PWM mode/complementary PWM mode. These register settings are ineffective for anything other than complementary PWM mode/reset-synchronized PWM mode.

|                |   |     |     |     |     |     |     |     |

**11.3.21 Timer Subcounter (TCNTS)**

TCNTS is a 16-bit read-only counter that is used only in complementary PWM mode.

The initial value of TCNTS is H'0000.

|                |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R | R | R | R | R | R | R | R |

Note: Accessing the TCNTS in 8-bit units is prohibited. Always access in 16-bit units.

11.3.22 Timer Dead Time Data Register (TDDR)

TDDR is a 16-bit register, used only in complementary PWM mode that specifies the TCNT\_3 and TCNT\_4 counter offset values. In complementary PWM mode, when the TCNT\_3 and TCNT\_4 counters are cleared and then restarted, the TDDR register value is loaded into the TCNT\_3 counter and the count operation starts.

The initial value of TDDR is H'FFFF.

Note: Accessing the TDDR in 8-bit units is prohibited. Always access in 16-bit units.

11.3.23 Timer Cycle Data Register (TCDR)

TCDR is a 16-bit register used only in complementary PWM mode. Set half the PWM carrier sync value (a value of two times TDDR + 3 or greater) as the TCDR register value. This register is constantly compared with the TCNTS counter in complementary PWM mode, and when a match occurs, the TCNTS counter switches direction (decrement to increment).

The initial value of TCDR is H'FFFF.

Note: Accessing the TCDR in 8-bit units is prohibited. Always access in 16-bit units.

11.3.24 Timer Cycle Buffer Register (TCBR)

TCBR is a 16-bit register used only in complementary PWM mode. It functions as a buffer register for the TCDR register. The TCBR register values are transferred to the TCDR register with the transfer timing set in the TMDR register.

Note: Accessing the TCBR in 8-bit units is prohibited. Always access in 16-bit units.

11.3.25 Timer Interrupt Skipping Set Register (TITCR)

TITCR is an 8-bit readable/writable register that enables or disables interrupt skipping and specifies the interrupt skipping count. The MTU2 has one TITCR.

| Bit    | Bit Name   | Initial value | R/W | Description                                                                                                                              |
|--------|------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | T3AEN      | 0             | R/W | T3AEN<br>Enables or disables TGIA_3 interrupt skipping.<br>0: TGIA_3 interrupt skipping disabled<br>1: TGIA_3 interrupt skipping enabled |
| 6 to 4 | 3ACOR[2:0] | 000           | R/W | These bits specify the TGIA_3 interrupt skipping count within the range from 0 to 7.*<br>For details, see table 11.38.                   |
| 3      | T4VEN      | 0             | R/W | T4VEN<br>Enables or disables TCIV_4 interrupt skipping.<br>0: TCIV_4 interrupt skipping disabled<br>1: TCIV_4 interrupt skipping enabled |

| Bit    | Bit Name   | Initial value | R/W | Description                                                                                                            |
|--------|------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------|
| 2 to 0 | 4VCOR[2:0] | 000           | R/W | These bits specify the TCIV_4 interrupt skipping count within the range from 0 to 7.*<br>For details, see table 11.39. |

Note: \* When 0 is specified for the interrupt skipping count, no interrupt skipping will be performed. Before changing the interrupt skipping count, be sure to clear the T3AEN and T4VEN bits to 0 to clear the skipping counter (TICNT).

**Table 11.38 Setting of Interrupt Skipping Count by Bits 3ACOR2 to 3ACOR0**

| Bit 6  | Bit 5  | Bit 4  |                                                |
|--------|--------|--------|------------------------------------------------|
| 3ACOR2 | 3ACOR1 | 3ACOR0 | Description                                    |
| 0      | 0      | 0      | Does not skip TGIA_3 interrupts.               |
| 0      | 0      | 1      | Sets the TGIA_3 interrupt skipping count to 1. |
| 0      | 1      | 0      | Sets the TGIA_3 interrupt skipping count to 2. |
| 0      | 1      | 1      | Sets the TGIA_3 interrupt skipping count to 3. |
| 1      | 0      | 0      | Sets the TGIA_3 interrupt skipping count to 4. |
| 1      | 0      | 1      | Sets the TGIA_3 interrupt skipping count to 5. |
| 1      | 1      | 0      | Sets the TGIA_3 interrupt skipping count to 6. |
| 1      | 1      | 1      | Sets the TGIA_3 interrupt skipping count to 7. |

**Table 11.39 Setting of Interrupt Skipping Count by Bits 4VCOR2 to 4VCOR0**

| Bit 2  | Bit 1  | Bit 0  |                                                |
|--------|--------|--------|------------------------------------------------|
| 4VCOR2 | 4VCOR1 | 4VCOR0 | Description                                    |
| 0      | 0      | 0      | Does not skip TCIV_4 interrupts.               |
| 0      | 0      | 1      | Sets the TCIV_4 interrupt skipping count to 1. |
| 0      | 1      | 0      | Sets the TCIV_4 interrupt skipping count to 2. |
| 0      | 1      | 1      | Sets the TCIV_4 interrupt skipping count to 3. |
| 1      | 0      | 0      | Sets the TCIV_4 interrupt skipping count to 4. |
| 1      | 0      | 1      | Sets the TCIV_4 interrupt skipping count to 5. |
| 1      | 1      | 0      | Sets the TCIV_4 interrupt skipping count to 6. |
| 1      | 1      | 1      | Sets the TCIV_4 interrupt skipping count to 7. |

### 11.3.26 Timer Interrupt Skipping Counter (TITCNT)

TITCNT is an 8-bit readable/writable counter. The MTU2 has one TITCNT. TITCNT retains its value even after stopping the count operation of TCNT\_3 and TCNT\_4.

|                |   |            |   |   |   |            |   |   |
|----------------|---|------------|---|---|---|------------|---|---|
| Bit:           | 7 | 6          | 5 | 4 | 3 | 2          | 1 | 0 |
|                | - | 3ACNT[2:0] |   |   | - | 4VCNT[2:0] |   |   |
| Initial value: | 0 | 0          | 0 | 0 | 0 | 0          | 0 | 0 |
| R/W:           | R | R          | R | R | R | R          | R | R |

| Bit    | Bit Name   | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 2 to 0 | 4VCNT[2:0] | 000           | R   | TCIV_4 Interrupt Counter<br>While the T4VEN bit in TITCR is set to 1, the count in these bits is incremented every time a TCIV_4 interrupt occurs.<br>[Clearing conditions] <ul style="list-style-type: none"> <li>When the 4VCNT2 to 4VCNT0 value in TITCNT matches the 4VCOR2 to 4VCOR2 value in TITCR</li> <li>When the T4VEN bit in TITCR is cleared to 0</li> <li>When the 4VCOR2 to 4VCOR2 bits in TITCR are cleared to 0</li> </ul> |

Note: To clear the TITCNT, clear the bits T3AEN and T4VEN in TITCR to 0.

### 11.3.27 Timer Buffer Transfer Set Register (TBTER)

TBTER is an 8-bit readable/writable register that enables or disables transfer from the buffer registers\* used in complementary PWM mode to the temporary registers and specifies whether to link the transfer with interrupt skipping operation. The MTU2 has one TBTER.

|                |   |   |   |   |   |   |          |     |
|----------------|---|---|---|---|---|---|----------|-----|

Note: \* Applicable buffer registers:  
TGR3\_3, TGRD\_3, TGR3\_4, TGRD\_4, and TCBR

**Table 11.40 Setting of Bits BTE1 and BTE0**

| Bit 1 | Bit 0 |                                                                                                                                                       |
|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| BTE1  | BTE0  | Description                                                                                                                                           |
| 0     | 0     | Enables transfer from the buffer registers to the temporary registers* <sup>1</sup> and does not link the transfer with interrupt skipping operation. |
| 0     | 1     | Disables transfer from the buffer registers to the temporary registers.                                                                               |
| 1     | 0     | Links transfer from the buffer registers to the temporary registers with interrupt skipping operation.* <sup>2</sup>                                  |
| 1     | 1     | Setting prohibited                                                                                                                                    |

- Notes: 1. Data is transferred according to the MD3 to MD0 bit setting in TMDR. For details, refer to section 11.4.8, Complementary PWM Mode.
2. When interrupt skipping is disabled (the T3AEN and T4VEN bits are cleared to 0 in the timer interrupt skipping set register (TITCR) or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), be sure to disable link of buffer transfer with interrupt skipping (clear the BTE1 bit in the timer buffer transfer set register (TBTER) to 0). If link with interrupt skipping is enabled while interrupt skipping is disabled, buffer transfer will not be performed.

### 11.3.28 Timer Dead Time Enable Register (TDER)

TDER is an 8-bit readable/writable register that controls dead time generation in complementary PWM mode. The MTU2 has one TDER in channel 3. TDER must be modified only while TCNT stops.

|                |   |   |   |   |   |   |   |       |
|----------------|---|---|---|---|---|---|---|-------|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|                | - | - | - | - | - | - | - | TDER  |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1     |
| R/W:           | R | R | R | R | R | R | R | R/(W) |

| Bit    | Bit Name | Initial Value | R/W   | Description                                                                                                                                                                                                                                             |
|--------|----------|---------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 1 | —        | All 0         | R     | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                                                                                                        |
| 0      | TDER     | 1             | R/(W) | Dead Time Enable<br>Specifies whether to generate dead time.<br>0: Does not generate dead time<br>1: Generates dead time*<br>[Clearing condition]<br><ul style="list-style-type: none"> <li>When 0 is written to TDER after reading TDER = 1</li> </ul> |

Note: \* TDDR must be set to 1 or a larger value.

11.3.29 Timer Waveform Control Register (TWCR)

TWCR is an 8-bit readable/writable register that controls the waveform when synchronous counter clearing occurs in TCNT\_3 and TCNT\_4 in complementary PWM mode and specifies whether to clear the counters at TGRA\_3 compare match. The CCE bit and WRE bit in TWCR must be modified only while TCNT stops.

|                |       |   |   |   |   |   |   |       |
|----------------|-------|---|---|---|---|---|---|-------|
| Bit:           | 7     | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|                | CCE   | - | - | - | - | - | - | WRE   |
| Initial value: | 0*    | 0 | 0 | 0 | 0 | 0 | 0 | 0     |
| R/W:           | R/(W) | R | R | R | R | R | R | R/(W) |

Note: \* Do not set to 1 when complementary PWM mode is not selected.

| Bit    | Bit Name | Initial Value | R/W   | Description                                                                                                                                                                                                                                                                                                                                    |

### 11.3.30 Bus Master Interface

The timer counters (TCNT), general registers (TGR), timer subcounter (TCNTS), timer cycle buffer register (TCBR), timer dead time data register (TDDR), timer cycle data register (TCDR), timer A/D converter start request control register (TADCR), timer A/D converter start request cycle set registers (TADCOR), and timer A/D converter start request cycle set buffer registers (TADCOBR) are 16-bit registers. A 16-bit data bus to the bus master enables 16-bit read/writes. 8-bit read/write is not possible. Always access in 16-bit units.

All registers other than the above registers are 8-bit registers. These are connected to the CPU by a 16-bit data bus, so 16-bit read/writes and 8-bit read/writes are both possible.

## 11.4 Operation

### 11.4.1 Basic Functions

Each channel has a TCNT and TGR register. TCNT performs up-counting, and is also capable of free-running operation, cycle counting, and external event counting.

Each TGR can be used as an input capture register or output compare register.

Always select MTU2 external pins set function using the pin function controller (PFC).

#### (1) Counter Operation

When one of bits CST0 to CST4 in TSTR is set to 1, the TCNT counter for the corresponding channel begins counting. TCNT can operate as a free-running counter, periodic counter, for example.

#### (a) Example of Count Operation Setting Procedure

Figure 11.4 shows an example of the count operation setting procedure.

**Figure 11.4 Example of Counter Operation Setting Procedure**

**(b) Free-Running Count Operation and Periodic Count Operation:**

Immediately after a reset, the MTU2's TCNT counters are all designated as free-running counters. When the relevant bit in TSTR is set to 1 the corresponding TCNT counter starts up-count operation as a free-running counter. When TCNT overflows (from H'FFFF to H'0000), the TCFV bit in TSR is set to 1. If the value of the corresponding TCIEV bit in TIER is 1 at this point, the MTU2 requests an interrupt. After overflow, TCNT starts counting up again from H'0000.

Figure 11.5 illustrates free-running counter operation.

**Figure 11.5 Free-Running Counter Operation**

When compare match is selected as the TCNT clearing source, the TCNT counter for the relevant channel performs periodic count operation. The TGR register for setting the period is designated as an output compare register, and counter clearing by compare match is selected by means of bits CCLR0 to CCLR2 in TCR. After the settings have been made, TCNT starts up-count operation as a periodic counter when the corresponding bit in TSTR is set to 1. When the count value matches the value in TGR, the TGF bit in TSR is set to 1 and TCNT is cleared to H'0000.

If the value of the corresponding TGIE bit in TIER is 1 at this point, the MTU2 requests an interrupt. After a compare match, TCNT starts counting up again from H'0000.

Figure 11.6 illustrates periodic counter operation.

**Figure 11.6 Periodic Counter Operation**

## (2) Waveform Output by Compare Match

The MTU2 can perform 0, 1, or toggle output from the corresponding output pin using compare match.

### (a) Example of Setting Procedure for Waveform Output by Compare Match

Figure 11.7 shows an example of the setting procedure for waveform output by compare match

**Figure 11.7 Example of Setting Procedure for Waveform Output by Compare Match**

**(b) Examples of Waveform Output Operation:**

Figure 11.8 shows an example of 0 output/1 output.

In this example TCNT has been designated as a free-running counter, and settings have been made such that 1 is output by compare match A, and 0 is output by compare match B. When the set level and the pin level coincide, the pin level does not change.

**Figure 11.8 Example of 0 Output/1 Output Operation**

Figure 11.9 shows an example of toggle output.

In this example, TCNT has been designated as a periodic counter (with counter clearing on compare match B), and settings have been made such that the output is toggled by both compare match A and compare match B.

**Figure 11.9 Example of Toggle Output Operation**

### (3) Input Capture Function

The TCNT value can be transferred to TGR on detection of the TIOC pin input edge.

Rising edge, falling edge, or both edges can be selected as the detected edge. For channels 0 and 1, it is also possible to specify another channel's counter input clock or compare match signal as the input capture source.

Note: When another channel's counter input clock is used as the input capture input for channels 0 and 1,  $P\phi/1$  should not be selected as the counter input clock used for input capture input. Input capture will not be generated if  $P\phi/1$  is selected.

#### (a) Example of Input Capture Operation Setting Procedure

Figure 11.10 shows an example of the input capture operation setting procedure.

**Figure 11.10 Example of Input Capture Operation Setting Procedure**

### (b) Example of Input Capture Operation

Figure 11.11 shows an example of input capture operation.

In this example both rising and falling edges have been selected as the TIOCA pin input capture input edge, the falling edge has been selected as the TIOCB pin input capture input edge, and counter clearing by TGRB input capture has been designated for TCNT.

**Figure 11.11 Example of Input Capture Operation**

## 11.4.2 Synchronous Operation

In synchronous operation, the values in a number of TCNT counters can be rewritten simultaneously (synchronous presetting). Also, a number of TCNT counters can be cleared simultaneously by making the appropriate setting in TCR (synchronous clearing).

Synchronous operation enables TGR to be incremented with respect to a single time base.

Channels 0 to 4 can all be designated for synchronous operation.

### (1) Example of Synchronous Operation Setting Procedure

Figure 11.12 shows an example of the synchronous operation setting procedure.

**Figure 11.12 Example of Synchronous Operation Setting Procedure**

## (2) Example of Synchronous Operation

Figure 11.13 shows an example of synchronous operation.

In this example, synchronous operation and PWM mode 1 have been designated for channels 0 to 2, TGRB\_0 compare match has been set as the channel 0 counter clearing source, and synchronous clearing has been set for the channel 1 and 2 counter clearing source.

Three-phase PWM waveforms are output from pins TIOC0A, TIOC1A, and TIOC2A. At this time, synchronous presetting, and synchronous clearing by TGRB\_0 compare match, are performed for channel 0 to 2 TCNT counters, and the data set in TGRB\_0 is used as the PWM cycle.

For details of PWM modes, see section 11.4.5, PWM Modes.

**Figure 11.13 Example of Synchronous Operation**

### 11.4.3 Buffer Operation

Buffer operation, provided for channels 0, 3, and 4, enables TGRC and TGRD to be used as buffer registers. In channel 0, TGRF can also be used as a buffer register.

Buffer operation differs depending on whether TGR has been designated as an input capture register or as a compare match register.

Note: TGRE\_0 cannot be designated as an input capture register and can only operate as a compare match register.

Table 11.41 shows the register combinations used in buffer operation.

**Table 11.41 Register Combinations in Buffer Operation**

| Channel | Timer General Register | Buffer Register |
|---------|------------------------|-----------------|
| 0       | TGRA_0                 | TGRC_0          |
|         | TGRB_0                 | TGRD_0          |
|         | TGRE_0                 | TGRF_0          |
| 3       | TGRA_3                 | TGRC_3          |
|         | TGRB_3                 | TGRD_3          |
| 4       | TGRA_4                 | TGRC_4          |
|         | TGRB_4                 | TGRD_4          |

- When TGR is an output compare register

When a compare match occurs, the value in the buffer register for the corresponding channel is transferred to the timer general register.

This operation is illustrated in figure 11.14.

**Figure 11.14 Compare Match Buffer Operation**

- When TGR is an input capture register

When input capture occurs, the value in TCNT is transferred to TGR and the value previously held in the timer general register is transferred to the buffer register.

This operation is illustrated in figure 11.15.

**Figure 11.15 Input Capture Buffer Operation**

### (1) Example of Buffer Operation Setting Procedure

Figure 11.16 shows an example of the buffer operation setting procedure.

**Figure 11.16 Example of Buffer Operation Setting Procedure**

## (2) Examples of Buffer Operation

### (a) When TGR is an output compare register

Figure 11.17 shows an operation example in which PWM mode 1 has been designated for channel 0, and buffer operation has been designated for TGRA and TGRC. The settings used in this example are TCNT clearing by compare match B, 1 output at compare match A, and 0 output at compare match B. In this example, the TTSA bit in TBTM is cleared to 0.

As buffer operation has been set, when compare match A occurs the output changes and the value in buffer register TGRC is simultaneously transferred to timer general register TGRA. This operation is repeated each time that compare match A occurs.

For details of PWM modes, see section 11.4.5, PWM Modes.

**Figure 11.17 Example of Buffer Operation (1)**

### (b) When TGR is an input capture register

Figure 11.18 shows an operation example in which TGRA has been designated as an input capture register, and buffer operation has been designated for TGRA and TGRC.

Counter clearing by TGRA input capture has been set for TCNT, and both rising and falling edges have been selected as the TIOCA pin input capture input edge.

As buffer operation has been set, when the TCNT value is stored in TGRA upon the occurrence of input capture A, the value previously stored in TGRA is simultaneously transferred to TGRC.

**Figure 11.18 Example of Buffer Operation (2)**

### (3) Selecting Timing for Transfer from Buffer Registers to Timer General Registers in Buffer Operation

The timing for transfer from buffer registers to timer general registers can be selected in PWM mode 1 or 2 for channel 0 or in PWM mode 1 for channels 3 and 4 by setting the buffer operation transfer mode registers (TBTM\_0, TBTM\_3, and TBTM\_4). Either compare match (initial setting) or TCNT clearing can be selected for the transfer timing. TCNT clearing as transfer timing is one of the following cases.

- When TCNT overflows (H'FFFF to H'0000)
- When H'0000 is written to TCNT during counting
- When TCNT is cleared to H'0000 under the condition specified in the CCLR2 to CCLR0 bits in TCR

Note: TBTM must be modified only while TCNT stops.

Figure 11.19 shows an operation example in which PWM mode 1 is designated for channel 0 and buffer operation is designated for TGRA\_0 and TGRC\_0. The settings used in this example are TCNT\_0 clearing by compare match B, 1 output at compare match A, and 0 output at compare match B. The TTSA bit in TBTM\_0 is set to 1.

**Figure 11.19 Example of Buffer Operation When TCNT\_0 Clearing is Selected for TGRC\_0 to TGRA\_0 Transfer Timing**

#### 11.4.4 Cascaded Operation

In cascaded operation, two 16-bit counters for different channels are used together as a 32-bit counter.

This function works by counting the channel 1 counter clock upon overflow/underflow of TCNT\_2 as set in bits TPSC0 to TPSC2 in TCR.

Underflow occurs only when the lower 16-bit TCNT is in phase-counting mode.

Table 11.42 shows the register combinations used in cascaded operation.

Note: When phase counting mode is set for channel 1, the counter clock setting is invalid and the counters operates independently in phase counting mode.

**Table 11.42 Cascaded Combinations**

| Combination      | Upper 16 Bits | Lower 16 Bits |
|------------------|---------------|---------------|
| Channels 1 and 2 | TCNT_1        | TCNT_2        |

For simultaneous input capture of TCNT\_1 and TCNT\_2 during cascaded operation, additional input capture input pins can be specified by the input capture control register (TICCR). The edge detection that is the condition for input capture uses a signal representing the logical OR of the original input pin and the added input pins. For details, see (4) Cascaded Operation Example (c).

For input capture in cascade connection, refer to section 11.7.22, Simultaneous Capture of TCNT\_1 and TCNT\_2 in Cascade Connection.

Table 11.43 show the TICCRR setting and input capture input pins.

**Table 11.43 TICCRR Setting and Input Capture Input Pins**

| Target Input Capture                | TICCRR Setting               | Input Capture Input Pins |
|-------------------------------------|------------------------------|--------------------------|
| Input capture from TCNT_1 to TGRA_1 | I2AE bit = 0 (initial value) | TIOC1A                   |
|                                     | I2AE bit = 1                 | TIOC1A, TIOC2A           |
| Input capture from TCNT_1 to TGRB_1 | I2BE bit = 0 (initial value) | TIOC1B                   |
|                                     | I2BE bit = 1                 | TIOC1B, TIOC2B           |
| Input capture from TCNT_2 to TGRA_2 | I1AE bit = 0 (initial value) | TIOC2A                   |
|                                     | I1AE bit = 1                 | TIOC2A, TIOC1A           |
| Input capture from TCNT_2 to TGRB_2 | I1BE bit = 0 (initial value) | TIOC2B                   |
|                                     | I1BE bit = 1                 | TIOC2B, TIOC1B           |

### (1) Example of Cascaded Operation Setting Procedure

Figure 11.20 shows an example of the setting procedure for cascaded operation.

**Figure 11.20 Cascaded Operation Setting Procedure**

### (2) Cascaded Operation Example (a)

Figure 11.21 illustrates the operation when TCNT\_2 overflow/underflow counting has been set for TCNT\_1 and phase counting mode has been designated for channel 2.

TCNT\_1 is incremented by TCNT\_2 overflow and decremented by TCNT\_2 underflow.

**Figure 11.21 Cascaded Operation Example (a)**

### (3) Cascaded Operation Example (b)

Figure 11.22 illustrates the operation when TCNT\_1 and TCNT\_2 have been cascaded and the I2AE bit in TICC\_R has been set to 1 to include the TIOC2A pin in the TGRA\_1 input capture conditions. In this example, the IOA0 to IOA3 bits in TIOR\_1 have selected the TIOC1A rising edge for the input capture timing while the IOA0 to IOA3 bits in TIOR\_2 have selected the TIOC2A rising edge for the input capture timing.

Under these conditions, the rising edge of both TIOC1A and TIOC2A is used for the TGRA\_1 input capture condition. For the TGRA\_2 input capture condition, the TIOC2A rising edge is used.

**Figure 11.22 Cascaded Operation Example (b)**

#### (4) Cascaded Operation Example (c)

Figure 11.23 illustrates the operation when TCNT\_1 and TCNT\_2 have been cascaded and the I2AE and I1AE bits in TICCRR have been set to 1 to include the TIOC2A and TIOC1A pins in the TGRA\_1 and TGRA\_2 input capture conditions, respectively. In this example, the IOA0 to IOA3 bits in both TIOR\_1 and TIOR\_2 have selected both the rising and falling edges for the input capture timing. Under these conditions, the ORed result of TIOC1A and TIOC2A input is used for the TGRA\_1 and TGRA\_2 input capture conditions.

**Figure 11.23 Cascaded Operation Example (c)**

### (5) Cascaded Operation Example (d)

Figure 11.24 illustrates the operation when TCNT\_1 and TCNT\_2 have been cascaded and the I2AE bit in TICCRR has been set to 1 to include the TIOC2A pin in the TGRA\_1 input capture conditions. In this example, the IOA0 to IOA3 bits in TIOR\_1 have selected TGRA\_0 compare match or input capture occurrence for the input capture timing while the IOA0 to IOA3 bits in TIOR\_2 have selected the TIOC2A rising edge for the input capture timing.

Under these conditions, as TIOR\_1 has selected TGRA\_0 compare match or input capture occurrence for the input capture timing, the TIOC2A edge is not used for TGRA\_1 input capture condition although the I2AE bit in TICCRR has been set to 1.

**Figure 11.24 Cascaded Operation Example (d)**

### 11.4.5 PWM Modes

In PWM mode, PWM waveforms are output from the output pins. The output level can be selected as 0, 1, or toggle output in response to a compare match of each TGR.

TGR registers settings can be used to output a PWM waveform in the range of 0% to 100% duty.

Designating TGR compare match as the counter clearing source enables the period to be set in that register. All channels can be designated for PWM mode independently. Synchronous operation is also possible.

There are two PWM modes, as described below.

- PWM mode 1

PWM output is generated from the TIOCA and TIOCC pins by pairing TGRA with TGRB and TGRC with TGRD. The output specified by bits IOA0 to IOA3 and IOC0 to IOC3 in TIOR is output from the TIOCA and TIOCC pins at compare matches A and C, and the output specified by bits IOB0 to IOB3 and IOD0 to IOD3 in TIOR is output at compare matches B and D. The initial output value is the value set in TGRA or TGRC. If the set values of paired TGRs are identical, the output value does not change when a compare match occurs.

In PWM mode 1, a maximum 8-phase PWM output is possible.

- PWM mode 2

PWM output is generated using one TGR as the cycle register and the others as duty registers. The output specified in TIOR is performed by means of compare matches. Upon counter clearing by a cycle register compare match, the output value of each pin is the initial value set in TIOR. If the set values of the cycle and duty registers are identical, the output value does not change when a compare match occurs.

In PWM mode 2, a maximum 8-phase PWM output is possible in combination use with synchronous operation.

The correspondence between PWM output pins and registers is shown in table 11.44.

**Table 11.44 PWM Output Registers and Output Pins**

| Channel | Registers | Output Pins |               |
|---------|-----------|-------------|---------------|
|         |           | PWM Mode 1  | PWM Mode 2    |
| 0       | TGRA_0    | TIOC0A      | TIOC0A        |
|         | TGRB_0    |             | TIOC0B        |
|         | TGRC_0    | TIOC0C      | TIOC0C        |
|         | TGRD_0    |             | TIOC0D        |
| 1       | TGRA_1    | TIOC1A      | TIOC1A        |
|         | TGRB_1    |             | TIOC1B        |
| 2       | TGRA_2    | TIOC2A      | TIOC2A        |
|         | TGRB_2    |             | TIOC2B        |
| 3       | TGRA_3    | TIOC3A      | Cannot be set |
|         | TGRB_3    |             | Cannot be set |
|         | TGRC_3    | TIOC3C      | Cannot be set |
|         | TGRD_3    |             | Cannot be set |
| 4       | TGRA_4    | TIOC4A      | Cannot be set |
|         | TGRB_4    |             | Cannot be set |
|         | TGRC_4    | TIOC4C      | Cannot be set |
|         | TGRD_4    |             | Cannot be set |

Note: In PWM mode 2, PWM output is not possible for the TGR register in which the period is set.

## (1) Example of PWM Mode Setting Procedure

Figure 11.25 shows an example of the PWM mode setting procedure.

**Figure 11.25 Example of PWM Mode Setting Procedure**

## (2) Examples of PWM Mode Operation

Figure 11.26 shows an example of PWM mode 1 operation.

In this example, TGRA compare match is set as the TCNT clearing source, 0 is set for the TGRA initial output value and output value, and 1 is set as the TGRB output value.

In this case, the value set in TGRA is used as the period, and the values set in the TGRB registers are used as the duty levels.

**Figure 11.26 Example of PWM Mode Operation (1)**

Figure 11.27 shows an example of PWM mode 2 operation.

In this example, synchronous operation is designated for channels 0 and 1, TGRB\_1 compare match is set as the TCNT clearing source, and 0 is set for the initial output value and 1 for the output value of the other TGR registers (TGRA\_0 to TGRD\_0, TGRA\_1), outputting a 5-phase PWM waveform.

In this case, the value set in TGRB\_1 is used as the cycle, and the values set in the other TGRs are used as the duty levels.

**Figure 11.27 Example of PWM Mode Operation (2)**

Figure 11.28 shows examples of PWM waveform output with 0% duty and 100% duty in PWM mode.

**Figure 11.28 Example of PWM Mode Operation (3)**

### 11.4.6 Phase Counting Mode

In phase counting mode, the phase difference between two external clock inputs is detected and TCNT is incremented/decremented accordingly. This mode can be set for channels 1 and 2.

When phase counting mode is set, an external clock is selected as the counter input clock and TCNT operates as an up/down-counter regardless of the setting of bits TPSC0 to TPSC2 and bits CKEG0 and CKEG1 in TCR. However, the functions of bits CCLR0 and CCLR1 in TCR, and of TIOR, TIER, and TGR, are valid, and input capture/compare match and interrupt functions can be used.

This can be used for two-phase encoder pulse input.

If overflow occurs when TCNT is counting up, the TCFV flag in TSR is set; if underflow occurs when TCNT is counting down, the TCFU flag is set.

The TCFD bit in TSR is the count direction flag. Reading the TCFD flag reveals whether TCNT is counting up or down.

Table 11.45 shows the correspondence between external clock pins and channels.

**Table 11.45 Phase Counting Mode Clock Input Pins**

| Channels                                     | External Clock Pins |         |
|----------------------------------------------|---------------------|---------|
|                                              | A-Phase             | B-Phase |
| When channel 1 is set to phase counting mode | TCLKA               | TCLKB   |
| When channel 2 is set to phase counting mode | TCLKC               | TCLKD   |

#### (1) Example of Phase Counting Mode Setting Procedure

Figure 11.29 shows an example of the phase counting mode setting procedure.

**Figure 11.29 Example of Phase Counting Mode Setting Procedure**

(2) Examples of Phase Counting Mode Operation

In phase counting mode, TCNT counts up or down according to the phase difference between two external clocks. There are four modes, according to the count conditions.

(a) Phase counting mode 1

Figure 11.30 shows an example of phase counting mode 1 operation, and table 11.46 summarizes the TCNT up/down-count conditions.

Figure 11.30 Example of Phase Counting Mode 1 Operation

Table 11.46 Up/Down-Count Conditions in Phase Counting Mode 1

| TCLKA (Channel 1)<br>TCLKC (Channel 2) | TCLKB (Channel 1)<br>TCLKD (Channel 2) | Operation  |
|----------------------------------------|----------------------------------------|------------|
| High level                             |                                        | Up-count   |
| Low level                              |                                        |            |
|                                        | Low level                              |            |
|                                        | High level                             |            |
| High level                             |                                        | Down-count |
| Low level                              |                                        |            |
|                                        | High level                             |            |
|                                        | Low level                              |            |

[Legend]

- : Falling edge

(b) Phase counting mode 2

Figure 11.31 shows an example of phase counting mode 2 operation, and table 11.47 summarizes the TCNT up/down-count conditions.

Figure 11.31 Example of Phase Counting Mode 2 Operation

Table 11.47 Up/Down-Count Conditions in Phase Counting Mode 2

| TCLKA (Channel 1)<br>TCLKC (Channel 2) | TCLKB (Channel 1)<br>TCLKD (Channel 2) | Operation  |
|----------------------------------------|----------------------------------------|------------|
| High level                             |                                        | Don't care |
| Low level                              |                                        | Don't care |
|                                        | Low level                              | Don't care |
|                                        | High level                             | Up-count   |
| High level                             |                                        | Don't care |
| Low level                              |                                        | Don't care |
|                                        | High level                             | Don't care |
|                                        | Low level                              | Down-count |

[Legend]

- : Rising edge
- : Falling edge

(c) Phase counting mode 3

Figure 11.32 shows an example of phase counting mode 3 operation, and table 11.48 summarizes the TCNT up/down-count conditions.

Figure 11.32 Example of Phase Counting Mode 3 Operation

Table 11.48 Up/Down-Count Conditions in Phase Counting Mode 3

| TCLKA (Channel 1)<br>TCLKC (Channel 2) | TCLKB (Channel 1)<br>TCLKD (Channel 2) | Operation  |
|----------------------------------------|----------------------------------------|------------|
| High level                             |                                        | Don't care |
| Low level                              |                                        | Don't care |
|                                        | Low level                              | Don't care |
|                                        | High level                             | Up-count   |
| High level                             |                                        | Down-count |
| Low level                              |                                        | Don't care |
|                                        | High level                             | Don't care |
|                                        | Low level                              | Don't care |

[Legend]

- : Rising edge
- : Falling edge

(d) Phase counting mode 4

Figure 11.33 shows an example of phase counting mode 4 operation, and table 11.49 summarizes the TCNT up/down-count conditions.

Figure 11.33 Example of Phase Counting Mode 4 Operation

Table 11.49 Up/Down-Count Conditions in Phase Counting Mode 4

| TCLKA (Channel 1)<br>TCLKC (Channel 2) | TCLKB (Channel 1)<br>TCLKD (Channel 2) | Operation  |
|----------------------------------------|----------------------------------------|------------|
| High level                             |                                        | Up-count   |
| Low level                              |                                        |            |
|                                        | Low level                              | Don't care |
|                                        | High level                             |            |
| High level                             |                                        | Down-count |
| Low level                              |                                        |            |
|                                        | High level                             | Don't care |
|                                        | Low level                              |            |

[Legend]

- : Rising edge
- : Falling edge

### (3) Phase Counting Mode Application Example

Figure 11.34 shows an example in which channel 1 is in phase counting mode, and channel 1 is coupled with channel 0 to input servo motor 2-phase encoder pulses in order to detect position or speed.

Channel 1 is set to phase counting mode 1, and the encoder pulse A-phase and B-phase are input to TCLKA and TCLKB.

Channel 0 operates with TCNT counter clearing by TGRC\_0 compare match; TGRA\_0 and TGRC\_0 are used for the compare match function and are set with the speed control period and position control period. TGRB\_0 is used for input capture, with TGRB\_0 and TGRD\_0 operating in buffer mode. The channel 1 counter input clock is designated as the TGRB\_0 input capture source, and the pulse widths of 2-phase encoder 4-multiplication pulses are detected.

TGRA\_1 and TGRB\_1 for channel 1 are designated for input capture, and channel 0 TGRA\_0 and TGRC\_0 compare matches are selected as the input capture source and store the up/down-counter values for the control periods.

This procedure enables the accurate detection of position and speed.

**Figure 11.34 Phase Counting Mode Application Example**

### 11.4.7 Reset-Synchronized PWM Mode

In the reset-synchronized PWM mode, three-phase output of positive and negative PWM waveforms that share a common wave transition point can be obtained by combining channels 3 and 4.

When set for reset-synchronized PWM mode, the TIOC3B, TIOC3D, TIOC4A, TIOC4C, TIOC4B, and TIOC4D pins function as PWM output pins and TCNT3 functions as an upcounter.

Table 11.50 shows the PWM output pins used. Table 11.51 shows the settings of the registers.

**Table 11.50 Output Pins for Reset-Synchronized PWM Mode**

| Channel | Output Pin | Description                                                 |
|---------|------------|-------------------------------------------------------------|
| 3       | TIOC3B     | PWM output pin 1                                            |
|         | TIOC3D     | PWM output pin 1' (negative-phase waveform of PWM output 1) |
| 4       | TIOC4A     | PWM output pin 2                                            |
|         | TIOC4C     | PWM output pin 2' (negative-phase waveform of PWM output 2) |
|         | TIOC4B     | PWM output pin 3                                            |
|         | TIOC4D     | PWM output pin 3' (negative-phase waveform of PWM output 3) |

**Table 11.51 Register Settings for Reset-Synchronized PWM Mode**

| Register | Description of Setting                                                       |
|----------|------------------------------------------------------------------------------|
| TCNT_3   | Initial setting of H'0000                                                    |
| TCNT_4   | Initial setting of H'0000                                                    |
| TGRA_3   | Set count cycle for TCNT_3                                                   |
| TGRB_3   | Sets the turning point for PWM waveform output by the TIOC3B and TIOC3D pins |
| TGRA_4   | Sets the turning point for PWM waveform output by the TIOC4A and TIOC4C pins |
| TGRB_4   | Sets the turning point for PWM waveform output by the TIOC4B and TIOC4D pins |

## (1) Procedure for Selecting the Reset-Synchronized PWM Mode

Figure 11.35 shows an example of procedure for selecting the reset synchronized PWM mode.

**Figure 11.35 Procedure for Selecting Reset-Synchronized PWM Mode**

## (2) Reset-Synchronized PWM Mode Operation

Figure 11.36 shows an example of operation in the reset-synchronized PWM mode. TCNT\_3 and TCNT\_4 operate as upcounters. The counter is cleared when a TCNT\_3 and TGRA\_3 compare-match occurs, and then begins incrementing from H'0000. The PWM output pin output toggles with each occurrence of a TGRB\_3, TGRA\_4, TGRB\_4 compare-match, and upon counter clears.

**Figure 11.36 Reset-Synchronized PWM Mode Operation Example**  
(When TOCR's OLSN = 1 and OLSP = 1)

### 11.4.8 Complementary PWM Mode

In the complementary PWM mode, three-phase output of non-overlapping positive and negative PWM waveforms can be obtained by combining channels 3 and 4. PWM waveforms without non-overlapping interval are also available.

In complementary PWM mode, TIOC3B, TIOC3D, TIOC4A, TIOC4B, TIOC4C, and TIOC4D pins function as PWM output pins, the TIOC3A pin can be set for toggle output synchronized with the PWM period. TCNT\_3 and TCNT\_4 function as up/down counters.

Table 11.52 shows the PWM output pins used. Table 11.53 shows the settings of the registers used.

**Table 11.52 Output Pins for Complementary PWM Mode**

| Channel | Output Pin | Description                                                                                                                                      |
|---------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | TIOC3A     | Toggle output synchronized with PWM period (or I/O port)                                                                                         |
|         | TIOC3B     | PWM output pin 1                                                                                                                                 |
|         | TIOC3C     | I/O port*                                                                                                                                        |
|         | TIOC3D     | PWM output pin 1'<br>(non-overlapping negative-phase waveform of PWM output 1;<br>PWM output without non-overlapping interval is also available) |
| 4       | TIOC4A     | PWM output pin 2                                                                                                                                 |
|         | TIOC4B     | PWM output pin 3                                                                                                                                 |
|         | TIOC4C     | PWM output pin 2'<br>(non-overlapping negative-phase waveform of PWM output 2;<br>PWM output without non-overlapping interval is also available) |
|         | TIOC4D     | PWM output pin 3'<br>(non-overlapping negative-phase waveform of PWM output 3;<br>PWM output without non-overlapping interval is also available) |

Note: \* Avoid setting the TIOC3C pin as a timer I/O pin in the complementary PWM mode.

**Table 11.53 Register Settings for Complementary PWM Mode**

| Channel                              | Counter/Register | Description                                                  | Read/Write from CPU        |
|--------------------------------------|------------------|--------------------------------------------------------------|----------------------------|
| 3                                    | TCNT_3           | Start of up-count from value set in dead time register       | Maskable by TRWER setting* |
|                                      | TGRA_3           | Set TCNT_3 upper limit value (1/2 carrier cycle + dead time) | Maskable by TRWER setting* |
|                                      | TGRB_3           | PWM output 1 compare register                                | Maskable by TRWER setting* |
|                                      | TGRC_3           | TGRA_3 buffer register                                       | Always readable/writable   |
|                                      | TGRD_3           | PWM output 1/TGRB_3 buffer register                          | Always readable/writable   |
| 4                                    | TCNT_4           | Up-count start, initialized to H'0000                        | Maskable by TRWER setting* |
|                                      | TGRA_4           | PWM output 2 compare register                                | Maskable by TRWER setting* |
|                                      | TGRB_4           | PWM output 3 compare register                                | Maskable by TRWER setting* |

|                                      | TGRD_4           | PWM output 3/TGRB_4 buffer register                          | Always readable/writable   |
| Timer dead time data register (TDDR) |                  | Set TCNT_4 and TCNT_3 offset value (dead time value)         | Maskable by TRWER setting* |
| Timer cycle data register (TCDR)     |                  | Set TCNT_4 upper limit value (1/2 carrier cycle)             | Maskable by TRWER setting* |
| Timer cycle buffer register (TCBR)   |                  | TCDR buffer register                                         | Always readable/writable   |
| Subcounter (TCNTS)                   |                  | Subcounter for dead time generation                          | Read-only                  |
| Temporary register 1 (TEMP1)         |                  | PWM output 1/TGRB_3 temporary register                       | Not readable/writable      |
| Temporary register 2 (TEMP2)         |                  | PWM output 2/TGRA_4 temporary register                       | Not readable/writable      |
| Temporary register 3 (TEMP3)         |                  | PWM output 3/TGRB_4 temporary register                       | Not readable/writable      |

Note: \* Access can be enabled or disabled according to the setting of bit 0 (RWE) in TRWER (timer read/write enable register).

**Figure 11.37 Block Diagram of Channels 3 and 4 in Complementary PWM Mode**

## (1) Example of Complementary PWM Mode Setting Procedure

An example of the complementary PWM mode setting procedure is shown in figure 11.38.

**Figure 11.38 Example of Complementary PWM Mode Setting Procedure**

## (2) Outline of Complementary PWM Mode Operation

In complementary PWM mode, 6-phase PWM output is possible. Figure 11.39 illustrates counter operation in complementary PWM mode, and figure 11.40 shows an example of complementary PWM mode operation.

### (a) Counter Operation

In complementary PWM mode, three counters—TCNT\_3, TCNT\_4, and TCNTS—perform up/down-count operations.

TCNT\_3 is automatically initialized to the value set in TDDR when complementary PWM mode is selected and the CST bit in TSTR is 0.

When the CST bit is set to 1, TCNT\_3 counts up to the value set in TGRA\_3, then switches to down-counting when it matches TGRA\_3. When the TCNT3 value matches TDDR, the counter switches to up-counting, and the operation is repeated in this way.

TCNT\_4 is initialized to H'0000.

When the CST bit is set to 1, TCNT4 counts up in synchronization with TCNT\_3, and switches to down-counting when it matches TCDR. On reaching H'0000, TCNT4 switches to up-counting, and the operation is repeated in this way.

TCNTS is a read-only counter. It need not be initialized.

When TCNT\_3 matches TCDR during TCNT\_3 and TCNT\_4 up/down-counting, down-counting is started, and when TCNTS matches TCDR, the operation switches to up-counting. When TCNTS matches TGRA\_3, it is cleared to H'0000.

When TCNT\_4 matches TDDR during TCNT\_3 and TCNT\_4 down-counting, up-counting is started, and when TCNTS matches TDDR, the operation switches to down-counting. When TCNTS reaches H'0000, it is set with the value in TGRA\_3.

TCNTS is compared with the compare register and temporary register in which the PWM duty is set during the count operation only.

**Figure 11.39 Complementary PWM Mode Counter Operation**

### (b) Register Operation

In complementary PWM mode, nine registers are used, comprising compare registers, buffer registers, and temporary registers. Figure 11.40 shows an example of complementary PWM mode operation.

The registers which are constantly compared with the counters to perform PWM output are TGRB\_3, TGRA\_4, and TGRB\_4. When these registers match the counter, the value set in bits OLSN and OLSP in the timer output control register (TOCR) is output.

The buffer registers for these compare registers are TGRD\_3, TGRC\_4, and TGRD\_4.

Between a buffer register and compare register there is a temporary register. The temporary registers cannot be accessed by the CPU.

Data in a compare register is changed by writing the new data to the corresponding buffer register. The buffer registers can be read or written at any time.

The data written to a buffer register is constantly transferred to the temporary register in the Ta interval. Data is not transferred to the temporary register in the Tb interval. Data written to a buffer register in this interval is transferred to the temporary register at the end of the Tb interval.

The value transferred to a temporary register is transferred to the compare register when TCNTS for which the Tb interval ends matches TGRA\_3 when counting up, or H'0000 when counting down. The timing for transfer from the temporary register to the compare register can be selected with bits MD3 to MD0 in the timer mode register (TMDR). Figure 11.40 shows an example in which the mode is selected in which the change is made in the trough.

In the tb interval (tb1 in figure 11.40) in which data transfer to the temporary register is not performed, the temporary register has the same function as the compare register, and is compared

with the counter. In this interval, therefore, there are two compare match registers for one-phase output, with the compare register containing the pre-change data, and the temporary register containing the new data. In this interval, the three counters—TCNT\_3, TCNT\_4, and TCNTS—and two registers—compare register and temporary register—are compared, and PWM output controlled accordingly.

**Figure 11.40 Example of Complementary PWM Mode Operation**

### (c) Initialization

In complementary PWM mode, there are six registers that must be initialized. In addition, there is a register that specifies whether to generate dead time (it should be used only when dead time generation should be disabled).

Before setting complementary PWM mode with bits MD3 to MD0 in the timer mode register (TMDR), the following initial register values must be set.

TGRC\_3 operates as the buffer register for TGRA\_3, and should be set with  $1/2$  the PWM carrier cycle + dead time  $T_d$ . The timer cycle buffer register (TCBR) operates as the buffer register for the timer cycle data register (TCDR), and should be set with  $1/2$  the PWM carrier cycle. Set dead time  $T_d$  in the timer dead time data register (TDDR).

When dead time is not needed, the TDER bit in the timer dead time enable register (TDER) should be cleared to 0, TGRC\_3 and TGRA\_3 should be set to  $1/2$  the PWM carrier cycle + 1, and TDDR should be set to 1.

Set the respective initial PWM duty values in buffer registers TGRD\_3, TGRC\_4, and TGRD\_4.

The values set in the five buffer registers excluding TDDR are transferred simultaneously to the corresponding compare registers when complementary PWM mode is set.

Set TCNT\_4 to H'0000 before setting complementary PWM mode.

**Table 11.54 Registers and Counters Requiring Initialization**

| Register/Counter       | Set Value                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------|
| TGRC_3                 | $1/2$ PWM carrier cycle + dead time $T_d$ ( $1/2$ PWM carrier cycle + 1 when dead time generation is disabled by TDER) |
| TDDR                   | Dead time $T_d$ (1 when dead time generation is disabled by TDER)                                                      |
| TCBR                   | $1/2$ PWM carrier cycle                                                                                                |
| TGRD_3, TGRC_4, TGRD_4 | Initial PWM duty value for each phase                                                                                  |
| TCNT_4                 | H'0000                                                                                                                 |

Note: The TGRC\_3 set value must be the sum of  $1/2$  the PWM carrier cycle set in TCBR and dead time  $T_d$  set in TDDR. When dead time generation is disabled by TDER, TGRC\_3 must be set to  $1/2$  the PWM carrier cycle + 1.

#### (d) PWM Output Level Setting

In complementary PWM mode, the PWM pulse output level is set with bits OLSN and OLSP in timer output control register 1 (TOCR1) or bits OLS1P to OLS3P and OLS1N to OLS3N in timer output control register 2 (TOCR2).

The output level can be set for each of the three positive phases and three negative phases of 6-phase output.

Complementary PWM mode should be cleared before setting or changing output levels.

#### (e) Dead Time Setting

In complementary PWM mode, PWM pulses are output with a non-overlapping relationship between the positive and negative phases. This non-overlap time is called the dead time.

The non-overlap time is set in the timer dead time data register (TDDR). The value set in TDDR is used as the TCNT\_3 counter start value, and creates non-overlap between TCNT\_3 and TCNT\_4. Complementary PWM mode should be cleared before changing the contents of TDDR.

#### (f) Dead Time Suppressing

Dead time generation is suppressed by clearing the TDER bit in the timer dead time enable register (TDER) to 0. TDER can be cleared to 0 only when 0 is written to it after reading TDER = 1.

TGRA\_3 and TGRC\_3 should be set to  $1/2$  PWM carrier cycle + 1 and the timer dead time data register (TDDR) should be set to 1.

By the above settings, PWM waveforms without dead time can be obtained. Figure 11.41 shows an example of operation without dead time.

**Figure 11.41 Example of Operation without Dead Time**

### (g) PWM Cycle Setting

In complementary PWM mode, the PWM pulse cycle is set in two registers—TGRA\_3, in which the TCNT\_3 upper limit value is set, and TCDR, in which the TCNT\_4 upper limit value is set. The settings should be made so as to achieve the following relationship between these two registers:

- With dead time:  $\text{TGRA\_3 set value} = \text{TCDR set value} + \text{TDDR set value}$   
 $\text{TCDR set value} > \text{two times TDDR} + 2$
- Without dead time:  $\text{TGRA\_3 set value} = \text{TCDR set value} + 1$   
 $\text{TCDR set value} > 4$

The TGRA\_3 and TCDR settings are made by setting the values in buffer registers TGRC\_3 and TCBR. The values set in TGRC\_3 and TCBR are transferred simultaneously to TGRA\_3 and TCDR in accordance with the transfer timing selected with bits MD3 to MD0 in the timer mode register (TMDR).

The updated PWM cycle is reflected from the next cycle when the data update is performed at the crest, and from the current cycle when performed in the trough. Figure 11.42 illustrates the operation when the PWM cycle is updated at the crest.

See the following section, Register Data Updating, for the method of updating the data in each buffer register.

**Figure 11.42 Example of PWM Cycle Updating**

## (h) Register Data Updating

In complementary PWM mode, the buffer register is used to update the data in a compare register. The update data can be written to the buffer register at any time. There are five PWM duty and carrier cycle registers that have buffer registers and can be updated during operation.

There is a temporary register between each of these registers and its buffer register. When subcounter TCNTS is not counting, if buffer register data is updated, the temporary register value is also rewritten. Transfer is not performed from buffer registers to temporary registers when TCNTS is counting; in this case, the value written to a buffer register is transferred after TCNTS halts.

The temporary register value is transferred to the compare register at the data update timing set with bits MD3 to MD0 in the timer mode register (TMDR). Figure 11.43 shows an example of data updating in complementary PWM mode. This example shows the mode in which data updating is performed at both the counter crest and trough.

When rewriting buffer register data, a write to TGRD\_4 must be performed at the end of the update. Data transfer from the buffer registers to the temporary registers is performed simultaneously for all five registers after the write to TGRD\_4.

A write to TGRD\_4 must be performed after writing data to the registers to be updated, even when not updating all five registers, or when updating the TGRD\_4 data. In this case, the data written to TGRD\_4 should be the same as the data prior to the write operation.

Figure 11.43 Example of Data Update in Complementary PWM Mode

### (i) Initial Output in Complementary PWM Mode

In complementary PWM mode, the initial output is determined by the setting of bits OLSN and OLSP in timer output control register 1 (TOCR1) or bits OLS1N to OLS3N and OLS1P to OLS3P in timer output control register 2 (TOCR2).

This initial output is the PWM pulse non-active level, and is output from when complementary PWM mode is set with the timer mode register (TMDR) until TCNT\_4 exceeds the value set in the dead time register (TDDR). Figure 11.44 shows an example of the initial output in complementary PWM mode.

An example of the waveform when the initial PWM duty value is smaller than the TDDR value is shown in figure 11.45.

**Figure 11.44 Example of Initial Output in Complementary PWM Mode (1)**

**Timer output control register settings**

OLSN bit: 0 (initial output: high; active level: low)

OLSP bit: 0 (initial output: high; active level: low)

**Figure 11.45 Example of Initial Output in Complementary PWM Mode (2)**

## (j) Complementary PWM Mode PWM Output Generation Method

In complementary PWM mode, 3-phase output is performed of PWM waveforms with a non-overlap time between the positive and negative phases. This non-overlap time is called the dead time.

A PWM waveform is generated by output of the output level selected in the timer output control register in the event of a compare-match between a counter and compare register. While TCNTS is counting, compare register and temporary register values are simultaneously compared to create consecutive PWM pulses from 0 to 100%. The relative timing of on and off compare-match occurrence may vary, but the compare-match that turns off each phase takes precedence to secure the dead time and ensure that the positive phase and negative phase on times do not overlap. Figures 11.46 to 11.48 show examples of waveform generation in complementary PWM mode.

The positive phase/negative phase off timing is generated by a compare-match with the solid-line counter, and the on timing by a compare-match with the dotted-line counter operating with a delay of the dead time behind the solid-line counter. In the T1 period, compare-match **a** that turns off the negative phase has the highest priority, and compare-matches occurring prior to **a** are ignored. In the T2 period, compare-match **c** that turns off the positive phase has the highest priority, and compare-matches occurring prior to **c** are ignored.

In normal cases, compare-matches occur in the order **a** → **b** → **c** → **d** (or **c** → **d** → **a'** → **b'**), as shown in figure 11.46.

If compare-matches deviate from the **a** → **b** → **c** → **d** order, since the time for which the negative phase is off is less than twice the dead time, the figure shows the positive phase is not being turned on. If compare-matches deviate from the **c** → **d** → **a'** → **b'** order, since the time for which the positive phase is off is less than twice the dead time, the figure shows the negative phase is not being turned on.

If compare-match **c** occurs first following compare-match **a**, as shown in figure 11.47, compare-match **b** is ignored, and the negative phase is turned off by compare-match **d**. This is because turning off of the positive phase has priority due to the occurrence of compare-match **c** (positive phase off timing) before compare-match **b** (positive phase on timing) (consequently, the waveform does not change since the positive phase goes from off to off).

Similarly, in the example in figure 11.48, compare-match **a'** with the new data in the temporary register occurs before compare-match **c**, but other compare-matches occurring up to **c**, which turns off the positive phase, are ignored. As a result, the negative phase is not turned on.

Thus, in complementary PWM mode, compare-matches at turn-off timings take precedence, and turn-on timing compare-matches that occur before a turn-off timing compare-match are ignored.

**Figure 11.46 Example of Complementary PWM Mode Waveform Output (1)**

**Figure 11.47 Example of Complementary PWM Mode Waveform Output (2)**

**Figure 11.50 Example of Complementary PWM Mode 0% and 100% Waveform Output (2)**

**Figure 11.51 Example of Complementary PWM Mode 0% and 100% Waveform Output (3)**

**Figure 11.52 Example of Complementary PWM Mode 0% and 100% Waveform Output (4)**

**Figure 11.53 Example of Complementary PWM Mode 0% and 100% Waveform Output (5)**

### (k) Complementary PWM Mode 0% and 100% Duty Output

In complementary PWM mode, 0% and 100% duty cycles can be output as required. Figures 11.49 to 11.53 show output examples.

100% duty output is performed when the compare register value is set to H'0000. The waveform in this case has a positive phase with a 100% on-state. 0% duty output is performed when the compare register value is set to the same value as TGRA\_3. The waveform in this case has a positive phase with a 100% off-state.

On and off compare-matches occur simultaneously, but if a turn-on compare-match and turn-off compare-match for the same phase occur simultaneously, both compare-matches are ignored and the waveform does not change.

### (l) Toggle Output Synchronized with PWM Cycle

In complementary PWM mode, toggle output can be performed in synchronization with the PWM carrier cycle by setting the PSYE bit to 1 in the timer output control register (TOCR). An example of a toggle output waveform is shown in figure 11.54.

This output is toggled by a compare-match between TCNT\_3 and TGRA\_3 and a compare-match between TCNT4 and H'0000.

The output pin for this toggle output is the TIOC3A pin. The initial output is 1.

**Figure 11.54 Example of Toggle Output Waveform Synchronized with PWM Output**

### (m) Counter Clearing by Another Channel

In complementary PWM mode, by setting a mode for synchronization with another channel by means of the timer synchronous register (TSYR), and selecting synchronous clearing with bits CCLR2 to CCLR0 in the timer control register (TCR), it is possible to have TCNT\_3, TCNT\_4, and TCNTS cleared by another channel.

Figure 11.55 illustrates the operation.

Use of this function enables counter clearing and restarting to be performed by means of an external signal.

**Figure 11.55 Counter Clearing Synchronized with Another Channel**

### **(n) Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode**

Setting the WRE bit in TWCR to 1 suppresses initial output when synchronous counter clearing occurs in the Tb interval at the trough in complementary PWM mode and controls abrupt change in duty cycle at synchronous counter clearing.

Initial output suppression is applicable only when synchronous clearing occurs in the Tb interval at the trough as indicated by (10) or (11) in figure 11.56. When synchronous clearing occurs outside that interval, the initial value specified by the OLS bits in TOCR is output. Even in the Tb interval at the trough, if synchronous clearing occurs in the initial value output period (indicated by (1) in figure 11.56) immediately after the counters start operation, initial value output is not suppressed.

When using the initial output suppression function, make sure to set compare registers TGRB\_3, TGRA\_4, and TGRB\_4 to a value twice or more the setting of dead time data register TDDR. If synchronous clearing occurs with the compare registers set to a value less than twice the setting of TDDR, the PWM output dead time may be too short (or nonexistent) or illegal active-level PWM negative-phase output may occur during the initial output suppression interval. For details, see section 11.7.23, Notes on Output Waveform Control During Synchronous Counter Clearing in Complementary PWM Mode.

**Figure 11.56 Timing for Synchronous Counter Clearing**

- Example of Procedure for Setting Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode

An example of the procedure for setting output waveform control at synchronous counter clearing in complementary PWM mode is shown in figure 11.57.

**Figure 11.57 Example of Procedure for Setting Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode**

- Examples of Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode

Figures 11.58 to 11.61 show examples of output waveform control in which the MTU2 operates in complementary PWM mode and synchronous counter clearing is generated while the WRE bit in TWCR is set to 1. In the examples shown in figures 11.58 to 11.61, synchronous counter clearing occurs at timing (3), (6), (8), and (11) shown in figure 11.56, respectively.

**Figure 11.58 Example of Synchronous Clearing in Dead Time during Up-Counting (Timing (3) in Figure 11.56; Bit WRE of TWCR in MTU2 is 1)**

**Figure 11.59 Example of Synchronous Clearing in Interval Tb at Crest**  
(Timing (6) in Figure 11.56; Bit WRE of TWCR in MTU2 is 1)

**Figure 11.60 Example of Synchronous Clearing in Dead Time during Down-Counting**  
(Timing (8) in Figure 11.56; Bit WRE of TWCR is 1)

**Figure 11.61 Example of Synchronous Clearing in Interval Tb at Trough**  
**(Timing (11) in Figure 11.56; Bit WRE of TWCR is 1)**

### (o) Counter Clearing by TGRA\_3 Compare Match

In complementary PWM mode, by setting the CCE bit in the timer waveform control register (TWCR), it is possible to have TCNT\_3, TCNT\_4, and TCNTS cleared by TGRA\_3 compare match.

Figure 11.62 illustrates an operation example.

- Notes:
1. Use this function only in complementary PWM mode 1 (transfer at crest)
  2. Do not specify synchronous clearing by another channel (do not set the SYNC0 to SYNC4 bits in the timer synchronous register (TSYR) to 1.
  3. Do not set the PWM duty value to H'0000.
  4. Do not set the PSYE bit in timer output control register 1 (TOCR1) to 1.

**Figure 11.62 Example of Counter Clearing Operation by TGRA\_3 Compare Match**

(p) **Example of AC Synchronous Motor (Brushless DC Motor) Drive Waveform Output**

In complementary PWM mode, a brushless DC motor can easily be controlled using the timer gate control register (TGCR). Figures 11.63 to 11.66 show examples of brushless DC motor drive waveforms created using TGCR.

When output phase switching for a 3-phase brushless DC motor is performed by means of external signals detected with a Hall element, etc., clear the FB bit in TGCR to 0. In this case, the external signals indicating the polarity position are input to channel 0 timer input pins TIOC0A, TIOC0B, and TIOC0C (set with PFC). When an edge is detected at pin TIOC0A, TIOC0B, or TIOC0C, the output on/off state is switched automatically.

When the FB bit is 1, the output on/off state is switched when the UF, VF, or WF bit in TGCR is cleared to 0 or set to 1.

The drive waveforms are output from the complementary PWM mode 6-phase output pins. With this 6-phase output, in the case of on output, it is possible to use complementary PWM mode output and perform chopping output by setting the N bit or P bit to 1. When the N bit or P bit is 0, level output is selected.

The 6-phase output active level (on output level) can be set with the OLSN and OLSP bits in the timer output control register (TOCR) regardless of the setting of the N and P bits.

**Figure 11.63 Example of Output Phase Switching by External Input (1)**

**Figure 11.64 Example of Output Phase Switching by External Input (2)**

**Figure 11.65 Example of Output Phase Switching by Means of UF, VF, WF Bit Settings (1)**

**Figure 11.66 Example of Output Phase Switching by Means of UF, VF, WF Bit Settings (2)**

#### (q) A/D Converter Start Request Setting

In complementary PWM mode, an A/D converter start request can be issued using a TGRA\_3 compare-match, TCNT\_4 underflow (trough), or compare-match on a channel other than channels 3 and 4.

When start requests using a TGRA\_3 compare-match are specified, A/D conversion can be started at the crest of the TCNT\_3 count.

A/D converter start requests can be set by setting the TTGE bit to 1 in the timer interrupt enable register (TIER). To issue an A/D converter start request at a TCNT\_4 underflow (trough), set the TTGE2 bit in TIER\_4 to 1.

### (3) Interrupt Skipping in Complementary PWM Mode

Interrupts TGIA\_3 (at the crest) and TCIV\_4 (at the trough) in channels 3 and 4 can be skipped up to seven times by making settings in the timer interrupt skipping set register (TITCR).

Transfers from a buffer register to a temporary register or a compare register can be skipped in coordination with interrupt skipping by making settings in the timer buffer transfer register (TBTER). For the linkage with buffer registers, refer to description (c), Buffer Transfer Control Linked with Interrupt Skipping, below.

A/D converter start requests generated by the A/D converter start request delaying function can also be skipped in coordination with interrupt skipping by making settings in the timer A/D converter request control register (TADCR). For the linkage with the A/D converter start request delaying function, refer to section 11.4.9, A/D Converter Start Request Delaying Function.

The setting of the timer interrupt skipping setting register (TITCR) must be done while the TGIA\_3 and TCIV\_4 interrupt requests are disabled by the settings of TIER\_3 and TIER\_4 along with under the conditions in which TGFA\_3 and TCFV\_4 flag settings by compare match never occur. Before changing the skipping count, be sure to clear the T3AEN and T4VEN bits to 0 to clear the skipping counter.

#### (a) Example of Interrupt Skipping Operation Setting Procedure

Figure 11.67 shows an example of the interrupt skipping operation setting procedure. Figure 11.68 shows the periods during which interrupt skipping count can be changed.

**Figure 11.67 Example of Interrupt Skipping Operation Setting Procedure**

**Figure 11.68 Periods during which Interrupt Skipping Count Can Be Changed**

**(b) Example of Interrupt Skipping Operation**

Figure 11.69 shows an example of TGIA\_3 interrupt skipping in which the interrupt skipping count is set to three by the 3ACOR bit and the T3AEN bit is set to 1 in the timer interrupt skipping set register (TITCR).

**Figure 11.69 Example of Interrupt Skipping Operation**

### (c) Buffer Transfer Control Linked with Interrupt Skipping

In complementary PWM mode, whether to transfer data from a buffer register to a temporary register and whether to link the transfer with interrupt skipping can be specified with the BTE1 and BTE0 bits in the timer buffer transfer set register (TBTER).

Figure 11.70 shows an example of operation when buffer transfer is suppressed (BTE1 = 0 and BTE0 = 1). While this setting is valid, data is not transferred from the buffer register to the temporary register.

Figure 11.71 shows an example of operation when buffer transfer is linked with interrupt skipping (BTE1 = 1 and BTE0 = 0). While this setting is valid, data is not transferred from the buffer register outside the buffer transfer-enabled period.

Due to the buffer register rewrite timing after an interrupt, the timing of transfers from a buffer register to a temporary register differs from the timing of transfers from a temporary register to a general register.

Note that the buffer transfer-enabled period depends on the T3AEN and T4VEN bit settings in the timer interrupt skipping set register (TITCR). Figure 11.72 shows the relationship between the T3AEN and T4VEN bit settings in TITCR and buffer transfer-enabled period.

**Note:** This function must always be used in combination with interrupt skipping.

When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), make sure that buffer transfer is not linked with interrupt skipping (clear the BTE1 bit in the timer buffer transfer set register (TBTER) to 0). If buffer transfer is linked with interrupt skipping while interrupt skipping is disabled, buffer transfer is never performed.

## [Legend]

- (1) No data is transferred from the buffer register to the temporary register in the buffer transfer-disabled period (bits BTE1 and BTE0 in TBTER are set to 0 and 1, respectively).
- (2) Data is transferred from the temporary register to the general register even in the buffer transfer-disabled period.
- (3) After buffer transfer is enabled, data is transferred from the buffer register to the temporary register.

Note: \* When buffer transfer at the crest is selected.

**Figure 11.70 Example of Operation when Buffer Transfer Is Suppressed  
(BTE1 = 0 and BTE0 = 1)**

(1) When rewriting the buffer register within 1 carrier cycle from TGIA\_3 interrupt

(2) When rewriting the buffer register after passing 1 carrier cycle from TGIA\_3 interrupt

Note: The MD bits 3 to in TMDR3, buffer transfer at the crest is selected.  
The skipping count is set to two.  
T3AEN and T4VEN are set to 1 and 0.

**Figure 11.71 Example of Operation when Buffer Transfer Is Linked with Interrupt Skipping (BTE1 = 1 and BTE0 = 0)**

**Figure 11.72 Relationship between Bits T3AEN and T4VEN in TITCR and Buffer Transfer-Enabled Period**

#### (4) Complementary PWM Mode Output Protection Function

Complementary PWM mode output has the following protection function.

##### (a) Register and counter miswrite prevention function

With the exception of the buffer registers, which can be rewritten at any time, access by the CPU can be enabled or disabled for the mode registers, control registers, compare registers, and counters used in complementary PWM mode by means of the RWE bit in the timer read/write enable register (TRWER). The applicable registers are some (21 in total) of the registers in channels 3 and 4 shown in the following:

- TCR\_3 and TCR\_4, TMDR\_3 and TMDR\_4, TIORH\_3 and TIORH\_4, TIORL\_3 and TIORL\_4, TIER\_3 and TIER\_4, TCNT\_3 and TCNT\_4, TGRA\_3 and TGRA\_4, TGRB\_3 and TGRB\_4, TOER, TOCR, TGCR, TCDR, and TDDR.

This function enables miswriting due to CPU runaway to be prevented by disabling CPU access to the mode registers, control registers, and counters. When the applicable registers are read in the access-disabled state, undefined values are returned. Writing to these registers is ignored.

### 11.4.9 A/D Converter Start Request Delaying Function

A/D converter start requests can be issued in channel 4 by making settings in the timer A/D converter start request control register (TADCR), timer A/D converter start request cycle set registers (TADCORA\_4 and TADCORB\_4), and timer A/D converter start request cycle set buffer registers (TADCOBRA\_4 and TADCOBRB\_4).

The A/D converter start request delaying function compares TCNT\_4 with TADCORA\_4 or TADCORB\_4, and when their values match, the function issues a respective A/D converter start request (TRG4AN or TRG4BN).

A/D converter start requests (TRG4AN and TRG4BN) can be skipped in coordination with interrupt skipping by making settings in the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in TADCR.

- Example of Procedure for Specifying A/D Converter Start Request Delaying Function

Figure 11.73 shows an example of procedure for specifying the A/D converter start request delaying function.

**Figure 11.73 Example of Procedure for Specifying A/D Converter Start Request Delaying Function**

- Basic Operation Example of A/D Converter Start Request Delaying Function

Figure 11.74 shows a basic example of A/D converter request signal (TRG4AN) operation when the trough of TCNT\_4 is specified for the buffer transfer timing and an A/D converter start request signal is output during TCNT\_4 down-counting.

**Figure 11.74 Basic Example of A/D Converter Start Request Signal (TRG4AN) Operation**

- Buffer Transfer

The data in the timer A/D converter start request cycle set registers (TADCORA\_4 and TADCOBRB\_4) is updated by writing data to the timer A/D converter start request cycle set buffer registers (TADCOBRA\_4 and TADCOBRB\_4). Data is transferred from the buffer registers to the respective cycle set registers at the timing selected with the BF1 and BF0 bits in the timer A/D converter start request control register (TADCR\_4).

- A/D Converter Start Request Delaying Function Linked with Interrupt Skipping

A/D converter start requests (TRG4AN and TRG4BN) can be issued in coordination with interrupt skipping by making settings in the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR).

Figure 11.75 shows an example of A/D converter start request signal (TRG4AN) operation when TRG4AN output is enabled during TCNT\_4 up-counting and down-counting and A/D converter start requests are linked with interrupt skipping.

Figure 11.76 shows another example of A/D converter start request signal (TRG4AN) operation when TRG4AN output is enabled during TCNT\_4 up-counting and A/D converter start requests are linked with interrupt skipping.

**Note:** This function must be used in combination with interrupt skipping.

When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), make sure that A/D converter start requests are not linked with interrupt skipping (clear the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR) to 0).

**Figure 11.75 Example of A/D Converter Start Request Signal (TRG4AN) Operation Linked with Interrupt Skipping**

**Figure 11.76 Example of A/D Converter Start Request Signal (TRG4AN) Operation Linked with Interrupt Skipping**

### 11.4.10 TCNT Capture at Crest and/or Trough in Complementary PWM Operation

The TCNT value is captured in TGR at either the crest or trough or at both the crest and trough during complementary PWM operation. The timing for capturing in TGR can be selected by TIOR.

Figure 11.77 shows an example in which TCNT is used as a free-running counter without being cleared, and the TCNT value is captured in TGR at the specified timing (either crest or trough, or both crest and trough).

**Figure 11.77 TCNT Capturing at Crest and/or Trough in Complementary PWM Operation**

## 11.5 Interrupt Sources

### 11.5.1 Interrupt Sources and Priorities

There are three kinds of MTU2 interrupt source; TGR input capture/compare match, TCNT overflow, and TCNT underflow. Each interrupt source has its own status flag and enable/disable bit, allowing the generation of interrupt request signals to be enabled or disabled individually.

When an interrupt request is generated, the corresponding status flag in TSR is set to 1. If the corresponding enable/disable bit in TIER is set to 1 at this time, an interrupt is requested. The interrupt request is cleared by clearing the status flag to 0.

Relative channel priorities can be changed by the interrupt controller, however the priority order within a channel is fixed. For details, see section 6, Interrupt Controller (INTC).

Table 11.55 lists the MTU2 interrupt sources.

**Table 11.55 MTU2 Interrupts**

| Channel | Name   | Interrupt Source                   | Interrupt Flag | DMAC Activation | Priority  |
|---------|--------|------------------------------------|----------------|-----------------|-----------|
| 0       | TGIA_0 | TGRA_0 input capture/compare match | TGFA_0         | Possible        | High<br>↑ |
|         | TGIB_0 | TGRB_0 input capture/compare match | TGFB_0         | Not possible    |           |
|         | TGIC_0 | TGRC_0 input capture/compare match | TGFC_0         | Not possible    |           |
|         | TGID_0 | TGRD_0 input capture/compare match | TGFD_0         | Not possible    |           |
|         | TCIV_0 | TCNT_0 overflow                    | TCFV_0         | Not possible    |           |
|         | TGIE_0 | TGRE_0 compare match               | TGFE_0         | Not possible    |           |
|         | TGIF_0 | TGRF_0 compare match               | TGFF_0         | Not possible    |           |
| 1       | TGIA_1 | TGRA_1 input capture/compare match | TGFA_1         | Possible        | ↑<br>Low  |
|         | TGIB_1 | TGRB_1 input capture/compare match | TGFB_1         | Not possible    |           |
|         | TCIV_1 | TCNT_1 overflow                    | TCFV_1         | Not possible    |           |
|         | TCIU_1 | TCNT_1 underflow                   | TCFU_1         | Not possible    |           |
| 2       | TGIA_2 | TGRA_2 input capture/compare match | TGFA_2         | Possible        |           |
|         | TGIB_2 | TGRB_2 input capture/compare match | TGFB_2         | Not possible    |           |
|         | TCIV_2 | TCNT_2 overflow                    | TCFV_2         | Not possible    |           |
|         | TCIU_2 | TCNT_2 underflow                   | TCFU_2         | Not possible    |           |

| Channel | Name   | Interrupt Source                   | Interrupt Flag | DMAC Activation | Priority  |
|---------|--------|------------------------------------|----------------|-----------------|-----------|
| 3       | TGIA_3 | TGRA_3 input capture/compare match | TGFA_3         | Possible        | High<br>↑ |
|         | TGIB_3 | TGRB_3 input capture/compare match | TGFB_3         | Not possible    |           |
|         | TGIC_3 | TGRC_3 input capture/compare match | TGFC_3         | Not possible    |           |
|         | TGID_3 | TGRD_3 input capture/compare match | TGFD_3         | Not possible    |           |
|         | TCIV_3 | TCNT_3 overflow                    | TCFV_3         | Not possible    |           |
| 4       | TGIA_4 | TGRA_4 input capture/compare match | TGFA_4         | Possible        | ↓<br>Low  |
|         | TGIB_4 | TGRB_4 input capture/compare match | TGFB_4         | Not possible    |           |
|         | TGIC_4 | TGRC_4 input capture/compare match | TGFC_4         | Not possible    |           |
|         | TGID_4 | TGRD_4 input capture/compare match | TGFD_4         | Not possible    |           |
|         | TCIV_4 | TCNT_4 overflow/underflow          | TCFV_4         | Not possible    |           |

Note: This table shows the initial state immediately after a reset. The relative channel priorities can be changed by the interrupt controller.

### (1) Input Capture/Compare Match Interrupt

An interrupt is requested if the TGIE bit in TIER is set to 1 when the TGF flag in TSR is set to 1 by the occurrence of a TGR input capture/compare match on a particular channel. The interrupt request is cleared by clearing the TGF flag to 0. The MTU2 has eighteen input capture/compare match interrupts, six for channel 0, four each for channels 3 and 4, and two each for channels 1 and 2. The TGFE\_0 and TGFF\_0 flags in channel 0 are not set by the occurrence of an input capture.

### (2) Overflow Interrupt

An interrupt is requested if the TCIEV bit in TIER is set to 1 when the TCFV flag in TSR is set to 1 by the occurrence of TCNT overflow on a channel. The interrupt request is cleared by clearing the TCFV flag to 0. The MTU2 has five overflow interrupts, one for each channel.

### (3) Underflow Interrupt

An interrupt is requested if the TCIEU bit in TIER is set to 1 when the TCFU flag in TSR is set to 1 by the occurrence of TCNT underflow on a channel. The interrupt request is cleared by clearing the TCFU flag to 0. The MTU2 has two underflow interrupts, one each for channels 1 and 2.

### 11.5.2 DMAC Activation

The DMAC can be activated by the TGRA input capture/compare match interrupt in each channel. For details, see section 10, Direct Memory Access Controller (DMAC).

In the MTU2, a total of five TGRA input capture/compare match interrupts can be used as DMAC activation sources, one each for channels 0 to 4.

### 11.5.3 A/D Converter Activation

The A/D converter can be activated by one of the following three methods in the MTU2. Table 11.56 shows the relationship between interrupt sources and A/D converter start request signals.

#### (1) A/D Converter Activation by TGRA Input Capture/Compare Match or at TCNT\_4 Trough in Complementary PWM Mode

The A/D converter can be activated by the occurrence of a TGRA input capture/compare match in each channel. In addition, if complementary PWM operation is performed while the TTGE2 bit in TIER\_4 is set to 1, the A/D converter can be activated at the trough of TCNT\_4 count (TCNT\_4 = H'0000).

A/D converter start request signal TRGAN is issued to the A/D converter under either one of the following conditions.

- When the TGFA flag in TSR is set to 1 by the occurrence of a TGRA input capture/compare match on a particular channel while the TTGE bit in TIER is set to 1
- When the TCNT\_4 count reaches the trough (TCNT\_4 = H'0000) during complementary PWM operation while the TTGE2 bit in TIER\_4 is set to 1

When either condition is satisfied, if A/D converter start signal TRGAN from the MTU2 is selected as the trigger in the A/D converter, A/D conversion will start.

#### (2) A/D Converter Activation by Compare Match between TCNT\_0 and TGRE\_0

The A/D converter can be activated by generating A/D converter start request signal TRG0N when a compare match occurs between TCNT\_0 and TGRE\_0 in channel 0.

When the TGFE flag in TSR2\_0 is set to 1 by the occurrence of a compare match between TCNT\_0 and TGRE\_0 in channel 0 while the TTGE2 bit in TIER2\_0 is set to 1, A/D converter start request TGR0N is issued to the A/D converter. If A/D converter start signal TGR0N from the MTU2 is selected as the trigger in the A/D converter, A/D conversion will start.

### (3) A/D Converter Activation by A/D Converter Start Request Delaying Function

The A/D converter can be activated by generating A/D converter start request signal TRG4AN or TRG4BN when the TCNT\_4 count matches the TADCORA or TADCORB value if the UT4AE, DT4AE, UT4BE, and DT4BE bit in the A/D converter start request control register (TADCR) is set to 1. For details, refer to section 11.4.9, A/D Converter Start Request Delaying Function.

A/D conversion will start if A/D converter start signal TRG4AN from the MTU2 is selected as the trigger in the A/D converter when TRG4AN is generated or if TRG4BN from the MTU2 is selected as the trigger in the A/D converter when TRG4BN is generated.

**Table 11.56 Interrupt Sources and A/D Converter Start Request Signals**

| Target Registers   | Interrupt Source                        | A/D Converter Start Request Signal |
|--------------------|-----------------------------------------|------------------------------------|
| TGRA_0 and TCNT_0  | Input capture/compare match             | TRGAN                              |
| TGRA_1 and TCNT_1  |                                         |                                    |
| TGRA_2 and TCNT_2  |                                         |                                    |
| TGRA_3 and TCNT_3  |                                         |                                    |
| TGRA_4 and TCNT_4  |                                         |                                    |
| TCNT_4             | TCNT_4 Trough in complementary PWM mode |                                    |
| TGRE_0 and TCNT_0  | Compare match                           | TRG0N                              |
| TADCORA and TCNT_4 |                                         | TRG4AN                             |
| TADCORB and TCNT_4 |                                         | TRG4BN                             |

## 11.6 Operation Timing

### 11.6.1 Input/Output Timing

#### (1) TCNT Count Timing

Figure 11.78 shows TCNT count timing in internal clock operation, and figure 11.79 shows TCNT count timing in external clock operation (normal mode), and figure 11.80 shows TCNT count timing in external clock operation (phase counting mode).

**Figure 11.78 Count Timing in Internal Clock Operation**

**Figure 11.79 Count Timing in External Clock Operation**

**Figure 11.80 Count Timing in External Clock Operation (Phase Counting Mode)**

## (2) Output Compare Output Timing

A compare match signal is generated in the final state in which TCNT and TGR match (the point at which the count value matched by TCNT is updated). When a compare match signal is generated, the output value set in TIOR is output at the output compare output pin (TIOC pin). After a match between TCNT and TGR, the compare match signal is not generated until the TCNT input clock is generated.

Figure 11.81 shows output compare output timing (normal mode and PWM mode) and figure 11.82 shows output compare output timing (complementary PWM mode and reset synchronous PWM mode).

**Figure 11.81 Output Compare Output Timing (Normal Mode/PWM Mode)**

**Figure 11.82 Output Compare Output Timing**  
(Complementary PWM Mode/Reset Synchronous PWM Mode)

### (3) Input Capture Signal Timing

Figure 11.83 shows input capture signal timing.

**Figure 11.83 Input Capture Input Signal Timing**

#### (4) Timing for Counter Clearing by Compare Match/Input Capture

Figure 11.84 shows the timing when counter clearing on compare match is specified, and figure 11.85 shows the timing when counter clearing on input capture is specified.

**Figure 11.84 Counter Clear Timing (Compare Match)**

**Figure 11.85 Counter Clear Timing (Input Capture)**

### (5) Buffer Operation Timing

Figures 11.86 to 11.88 show the timing in buffer operation.

**Figure 11.86 Buffer Operation Timing (Compare Match)**

**Figure 11.87 Buffer Operation Timing (Input Capture)**

**Figure 11.88 Buffer Transfer Timing (when TCNT Cleared)**

#### (6) Buffer Transfer Timing (Complementary PWM Mode)

Figures 11.89 to 11.91 show the buffer transfer timing in complementary PWM mode.

**Figure 11.89 Transfer Timing from Buffer Register to Temporary Register (TCNTS Stop)**

**Figure 11.90 Transfer Timing from Buffer Register to Temporary Register (TCNTS Operating)**

**Figure 11.91 Transfer Timing from Temporary Register to Compare Register**

## 11.6.2 Interrupt Signal Timing

### (1) TGF Flag Setting Timing in Case of Compare Match

Figure 11.92 shows the timing for setting of the TGF flag in TSR on compare match, and TGI interrupt request signal timing.

**Figure 11.92 TGI Interrupt Timing (Compare Match)**

## (2) TGF Flag Setting Timing in Case of Input Capture

Figure 11.93 shows the timing for setting of the TGF flag in TSR on input capture, and TGI interrupt request signal timing.

**Figure 11.93 TGI Interrupt Timing (Input Capture)**

(3) TCFV Flag/TCFU Flag Setting Timing

Figure 11.94 shows the timing for setting of the TCFV flag in TSR on overflow, and TCIV interrupt request signal timing.

Figure 11.95 shows the timing for setting of the TCFU flag in TSR on underflow, and TCIU interrupt request signal timing.

Figure 11.94 TCIV Interrupt Setting Timing

Figure 11.95 TCIU Interrupt Setting Timing

#### (4) Status Flag Clearing Timing

After a status flag is read as 1 by the CPU, it is cleared by writing 0 to it. When the DMAC is activated, the flag is cleared automatically. Figure 11.96 shows the timing for status flag clearing by the CPU, and figure 11.97 shows the timing for status flag clearing by the DMAC.

**Figure 11.96 Timing for Status Flag Clearing by CPU**

**Figure 11.97 Timing for Status Flag Clearing by DMAC Activation**

## 11.7 Usage Notes

### 11.7.1 Module Standby Mode Setting

MTU2 operation can be disabled or enabled using the standby control register. The initial setting is for MTU2 operation to be halted. Register access is enabled by clearing module standby mode. For details, refer to section 28, Power-Down Modes.

### 11.7.2 Input Clock Restrictions

The input clock pulse width must be at least 1.5 states in the case of single-edge detection, and at least 2.5 states in the case of both-edge detection. The MTU2 will not operate properly at narrower pulse widths.

In phase counting mode, the phase difference and overlap between the two input clocks must be at least 1.5 states, and the pulse width must be at least 2.5 states. Figure 11.98 shows the input clock conditions in phase counting mode.

**Figure 11.98 Phase Difference, Overlap, and Pulse Width in Phase Counting Mode**

### 11.7.3 Caution on Period Setting

When counter clearing on compare match is set, TCNT is cleared in the final state in which it matches the TGR value (the point at which the count value matched by TCNT is updated). Consequently, the actual counter frequency is given by the following formula:

$$f = \frac{P\phi}{(N + 1)}$$

Where    f:        Counter frequency  
           P $\phi$ :      Peripheral clock operating frequency  
           N:        TGR set value

### 11.7.4 Contention between TCNT Write and Clear Operations

If the counter clear signal is generated in the T2 state of a TCNT write cycle, TCNT clearing takes precedence and the TCNT write is not performed.

Figure 11.99 shows the timing in this case.

**Figure 11.99 Contention between TCNT Write and Clear Operations**

### 11.7.5 Contention between TCNT Write and Increment Operations

If incrementing occurs in the T2 state of a TCNT write cycle, the TCNT write takes precedence and TCNT is not incremented.

Figure 11.100 shows the timing in this case.

**Figure 11.100 Contention between TCNT Write and Increment Operations**

### 11.7.6 Contention between TGR Write and Compare Match

If a compare match occurs in the T2 state of a TGR write cycle, the TGR write is executed and the compare match signal is also generated.

Figure 11.101 shows the timing in this case.

**Figure 11.101 Contention between TGR Write and Compare Match**

### 11.7.7 Contention between Buffer Register Write and Compare Match

If a compare match occurs in the T2 state of a TGR write cycle, the data that is transferred to TGR by the buffer operation is the data after write.

Figure 11.102 shows the timing in this case.

**Figure 11.102 Contention between Buffer Register Write and Compare Match**

### 11.7.8 Contention between Buffer Register Write and TCNT Clear

When the buffer transfer timing is set at the TCNT clear by the buffer transfer mode register (TBTM), if TCNT clear occurs in the T2 state of a TGR write cycle, the data that is transferred to TGR by the buffer operation is the data before write.

Figure 11.103 shows the timing in this case.

**Figure 11.103 Contention between Buffer Register Write and TCNT Clear**

### 11.7.9 Contention between TGR Read and Input Capture

If an input capture signal is generated in the T1 state of a TGR read cycle, the data that is read will be the data in the buffer before input capture transfer.

Figure 11.104 shows the timing in this case.

**Figure 11.104 Contention between TGR Read and Input Capture**

### 11.7.10 Contention between TGR Write and Input Capture

If an input capture signal is generated in the T2 state of a TGR write cycle, the input capture operation takes precedence and the write to TGR is not performed.

Figure 11.105 shows the timing in this case.

**Figure 11.105 Contention between TGR Write and Input Capture**

### 11.7.11 Contention between Buffer Register Write and Input Capture

If an input capture signal is generated in the T2 state of a buffer register write cycle, the buffer operation takes precedence and the write to the buffer register is not performed.

Figure 11.106 shows the timing in this case.

**Figure 11.106 Contention between Buffer Register Write and Input Capture**

### 11.7.12 TCNT2 Write and Overflow/Underflow Contention in Cascade Connection

With timer counters TCNT1 and TCNT2 in a cascade connection, when a contention occurs during TCNT\_1 count (during a TCNT\_2 overflow/underflow) in the T<sub>2</sub> state of the TCNT\_2 write cycle, the write to TCNT\_2 is conducted, and the TCNT\_1 count signal is disabled. At this point, if there is match with TGRA\_1 and the TCNT\_1 value, a compare signal is issued. Furthermore, when the TCNT\_1 count clock is selected as the input capture source of channel 0, TGRA\_0 to D\_0 carry out the input capture operation. In addition, when the compare match/input capture is selected as the input capture source of TGRB\_1, TGRB\_1 carries out input capture operation. The timing is shown in figure 11.107.

For cascade connections, be sure to synchronize settings for channels 1 and 2 when setting TCNT clearing.

**Figure 11.107 TCNT\_2 Write and Overflow/Underflow Contention with Cascade Connection**

### 11.7.13 Counter Value during Complementary PWM Mode Stop

When counting operation is suspended with TCNT\_3 and TCNT\_4 in complementary PWM mode, TCNT\_3 has the timer dead time register (TDDR) value, and TCNT\_4 is held at H'0000.

When restarting complementary PWM mode, counting begins automatically from the initialized state. This explanatory diagram is shown in figure 11.108.

When counting begins in another operating mode, be sure that TCNT\_3 and TCNT\_4 are set to the initial values.

**Figure 11.108 Counter Value during Complementary PWM Mode Stop**

### 11.7.14 Buffer Operation Setting in Complementary PWM Mode

In complementary PWM mode, conduct rewrites by buffer operation for the PWM cycle setting register (TGRA\_3), timer cycle data register (TCDR), and duty setting registers (TGRB\_3, TGRA\_4, and TGRB\_4).

In complementary PWM mode, channel 3 and channel 4 buffers operate in accordance with bit settings BFA and BFB of TMDR\_3. When TMDR\_3's BFA bit is set to 1, TGRC\_3 functions as a buffer register for TGRA\_3. At the same time, TGRC\_4 functions as the buffer register for TGRA\_4, and TCBR functions as the TCDR's buffer register.

### 11.7.15 Reset Sync PWM Mode Buffer Operation and Compare Match Flag

When setting buffer operation for reset sync PWM mode, set the BFA and BFB bits of TMDR\_4 to 0. The TIOC4C pin will be unable to produce its waveform output if the BFA bit of TMDR\_4 is set to 1.

In reset sync PWM mode, the channel 3 and channel 4 buffers operate in accordance with the BFA and BFB bit settings of TMDR\_3. For example, if the BFA bit of TMDR\_3 is set to 1, TGRC\_3 functions as the buffer register for TGRA\_3. At the same time, TGRC\_4 functions as the buffer register for TGRA\_4.

The TGFC bit and TGFD bit of TSR\_3 and TSR\_4 are not set when TGRC\_3 and TGRD\_3 are operating as buffer registers.

Figure 11.109 shows an example of operations for TGR\_3, TGR\_4, TIOC3, and TIOC4, with TMDR\_3's BFA and BFB bits set to 1, and TMDR\_4's BFA and BFB bits set to 0.

**Figure 11.109 Buffer Operation and Compare-Match Flags  
in Reset Synchronous PWM Mode**

### 11.7.16 Overflow Flags in Reset Synchronous PWM Mode

When set to reset synchronous PWM mode, TCNT\_3 and TCNT\_4 start counting when the CST3 bit of TSTR is set to 1. At this point, TCNT\_4's count clock source and count edge obey the TCR\_3 setting.

In reset synchronous PWM mode, with cycle register TGRA\_3's set value at H'FFFF, when specifying TGR3A compare-match for the counter clear source, TCNT\_3 and TCNT\_4 count up to H'FFFF, then a compare-match occurs with TGRA\_3, and TCNT\_3 and TCNT\_4 are both cleared. At this point, TSR's overflow flag TCFV bit is not set.

Figure 11.110 shows a TCFV bit operation example in reset synchronous PWM mode with a set value for cycle register TGRA\_3 of H'FFFF, when a TGRA\_3 compare-match has been specified without synchronous setting for the counter clear source.

**Figure 11.110 Reset Synchronous PWM Mode Overflow Flag**

### 11.7.17 Contention between Overflow/Underflow and Counter Clearing

If overflow/underflow and counter clearing occur simultaneously, the TCFV/TCFU flag in TSR is not set and TCNT clearing takes precedence.

Figure 11.111 shows the operation timing when a TGR compare match is specified as the clearing source, and when H'FFFF is set in TGR.

**Figure 11.111 Contention between Overflow and Counter Clearing**

### 11.7.18 Contention between TCNT Write and Overflow/Underflow

If there is an up-count or down-count in the T2 state of a TCNT write cycle, and overflow/underflow occurs, the TCNT write takes precedence and the TCFV/TCFU flag in TSR is not set.

Figure 11.112 shows the operation timing when there is contention between TCNT write and overflow.

**Figure 11.112 Contention between TCNT Write and Overflow**

### 11.7.19 Cautions on Transition from Normal Operation or PWM Mode 1 to Reset-Synchronized PWM Mode

When making a transition from channel 3 or 4 normal operation or PWM mode 1 to reset-synchronized PWM mode, if the counter is halted with the output pins (TIOC3B, TIOC3D, TIOC4A, TIOC4C, TIOC4B, TIOC4D) in the high-level state, followed by the transition to reset-synchronized PWM mode and operation in that mode, the initial pin output will not be correct.

When making a transition from normal operation to reset-synchronized PWM mode, write H'11 to registers TIORH\_3, TIORL\_3, TIORH\_4, and TIORL\_4 to initialize the output pins to low level output, then set an initial register value of H'00 before making the mode transition.

When making a transition from PWM mode 1 to reset-synchronized PWM mode, first switch to normal operation, then initialize the output pins to low level output and set an initial register value of H'00 before making the transition to reset-synchronized PWM mode.

### 11.7.20 Output Level in Complementary PWM Mode and Reset-Synchronized PWM Mode

When channels 3 and 4 are in complementary PWM mode or reset-synchronized PWM mode, the PWM waveform output level is set with the OLSP and OLSN bits in the timer output control register (TOCR). In the case of complementary PWM mode or reset-synchronized PWM mode, TIOR should be set to H'00.

### 11.7.21 Interrupts in Module Standby Mode

If module standby mode is entered when an interrupt has been requested, it will not be possible to clear the CPU interrupt source or the DMAC activation source. Interrupts should therefore be disabled before entering module standby mode.

### 11.7.22 Simultaneous Capture of TCNT\_1 and TCNT\_2 in Cascade Connection

When timer counters 1 and 2 (TCNT\_1 and TCNT\_2) are operated as a 32-bit counter in cascade connection, the cascade counter value cannot be captured successfully even if input-capture input is simultaneously done to TIOC1A and TIOC2A or to TIOC1B and TIOC2B. This is because the input timing of TIOC1A and TIOC2A or of TIOC1B and TIOC2B may not be the same when external input-capture signals to be input into TCNT\_1 and TCNT\_2 are taken in synchronization with the internal clock. For example, TCNT\_1 (the counter for upper 16 bits) does not capture the count-up value by overflow from TCNT\_2 (the counter for lower 16 bits) but captures the count value before the count-up. In this case, the values of TCNT\_1 = H'FFF1 and TCNT\_2 = H'0000 should be transferred to TGRA\_1 and TGRA\_2 or to TGRB\_1 and TGRB\_2, but the values of TCNT\_1 = H'FFF0 and TCNT\_2 = H'0000 are erroneously transferred.

### 11.7.23 Notes on Output Waveform Control During Synchronous Counter Clearing in Complementary PWM Mode

In complementary PWM mode, when output waveform control during synchronous counter clearing is enabled (WRE in the TWCR register set to 1), the following problems may occur when condition (1) or condition (2), below, is satisfied.

- Dead time for the PWM output pins may be too short (or nonexistent).
- Active-level output from the PWM negative-phase pins may occur outside the correct activelevel output interval

Condition (1): When synchronous clearing occurs in the PWM output dead time interval within initial output suppression interval (10) (figure 11.113).

Condition (2): When synchronous clearing occurs within initial output suppression interval (10) or (11) and  $TGRB\_3 \leq TDDR$ ,  $TGRA\_4 \leq TDDR$ , or  $TGRB\_4 \leq TDDR$  is true (figure 11.114)

**Figure 11.113 Condition (1) Synchronous Clearing Example**

**Figure 11.114 Condition (2) Synchronous Clearing Example**

The following workaround can be used to avoid these problems.

When using synchronous clearing, make sure to set compare registers TGRB\_3, TGRA\_4, and TGRB\_4 to a value twice or more the setting of dead time data register TDDR.

## 11.8 MTU2 Output Pin Initialization

### 11.8.1 Operating Modes

The MTU2 has the following six operating modes. Waveform output is possible in all of these modes.

- Normal mode (channels 0 to 4)
- PWM mode 1 (channels 0 to 4)
- PWM mode 2 (channels 0 to 2)
- Phase counting modes 1 to 4 (channels 1 and 2)
- Complementary PWM mode (channels 3 and 4)
- Reset-synchronized PWM mode (channels 3 and 4)

The MTU2 output pin initialization method for each of these modes is described in this section.

### 11.8.2 Reset Start Operation

The MTU2 output pins (TIOC\*) are initialized low by a power-on reset and in deep standby mode. Since MTU2 pin function selection is performed by the pin function controller (PFC), when the PFC is set, the MTU2 pin states at that point are output to the ports. When MTU2 output is selected by the PFC immediately after a reset, the MTU2 output initial level, low, is output directly at the port. When the active level is low, the system will operate at this point, and therefore the PFC setting should be made after initialization of the MTU2 output pins is completed.

Note: Channel number and port notation are substituted for \*.

### 11.8.3 Operation in Case of Re-Setting Due to Error During Operation, etc.

If an error occurs during MTU2 operation, MTU2 output should be cut by the system. Cutoff is performed by switching the pin output to port output with the PFC and outputting the inverse of the active level. The pin initialization procedures for re-setting due to an error during operation, etc., and the procedures for restarting in a different mode after re-setting, are shown below.

The MTU2 has six operating modes, as stated above. There are thus 36 mode transition combinations, but some transitions are not available with certain channel and mode combinations. Possible mode transition combinations are shown in table 11.57.

**Table 11.57 Mode Transition Combinations**

| Before | After  |      |      |      |           |      |
|--------|--------|------|------|------|-----------|------|
|        | Normal | PWM1 | PWM2 | PCM  | CPWM      | RPWM |
| Normal | (1)    | (2)  | (3)  | (4)  | (5)       | (6)  |
| PWM1   | (7)    | (8)  | (9)  | (10) | (11)      | (12) |
| PWM2   | (13)   | (14) | (15) | (16) | None      | None |
| PCM    | (17)   | (18) | (19) | (20) | None      | None |
| CPWM   | (21)   | (22) | None | None | (23) (24) | (25) |
| RPWM   | (26)   | (27) | None | None | (28)      | (29) |

[Legend]

Normal: Normal mode

PWM1: PWM mode 1

PWM2: PWM mode 2

PCM: Phase counting modes 1 to 4

CPWM: Complementary PWM mode

RPWM: Reset-synchronized PWM mode

### 11.8.4 Overview of Initialization Procedures and Mode Transitions in Case of Error during Operation, etc.

- When making a transition to a mode (Normal, PWM1, PWM2, PCM) in which the pin output level is selected by the timer I/O control register (TIOR) setting, initialize the pins by means of a TIOR setting.
- In PWM mode 1, since a waveform is not output to the TIOC\*B (TIOC \*D) pin, setting TIOR will not initialize the pins. If initialization is required, carry it out in normal mode, then switch to PWM mode 1.
- In PWM mode 2, since a waveform is not output to the cycle register pin, setting TIOR will not initialize the pins. If initialization is required, carry it out in normal mode, then switch to PWM mode 2.
- In normal mode or PWM mode 2, if TGRC and TGRD operate as buffer registers, setting TIOR will not initialize the buffer register pins. If initialization is required, clear buffer mode, carry out initialization, then set buffer mode again.
- In PWM mode 1, if either TGRC or TGRD operates as a buffer register, setting TIOR will not initialize the TGRC pin. To initialize the TGRC pin, clear buffer mode, carry out initialization, then set buffer mode again.
- When making a transition to a mode (CPWM, RPWM) in which the pin output level is selected by the timer output control register (TOCR) setting, switch to normal mode and perform initialization with TIOR, then restore TIOR to its initial value, and temporarily disable channel 3 and 4 output with the timer output master enable register (TOER). Then operate the unit in accordance with the mode setting procedure (TOCR setting, TMDR setting, TOER setting).

Note: Channel number is substituted for \* indicated in this article.

Pin initialization procedures are described below for the numbered combinations in table 11.57. The active level is assumed to be low.

### (1) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Normal Mode

Figure 11.115 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in normal mode after re-setting.

**Figure 11.115 Error Occurrence in Normal Mode, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. After a reset, the TMDR setting is for normal mode.
3. For channels 3 and 4, enable output with TOER before initializing the pins with TIOR.
4. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence.)
5. Set MTU2 output with the PFC.
6. The count operation is started by TSTR.
7. Output goes low on compare-match occurrence.
8. An error occurs.
9. Set port output with the PFC and output the inverse of the active level.
10. The count operation is stopped by TSTR.
11. Not necessary when restarting in normal mode.
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

## (2) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 11.116 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.116 Error Occurrence in Normal Mode, Recovery in PWM Mode 1**

1 to 10 are the same as in figure 11.115.

11. Set PWM mode 1.
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC\*B side is not initialized. If initialization is required, initialize in normal mode, then switch to PWM mode 1.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

### (3) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in PWM Mode 2

Figure 11.117 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in PWM mode 2 after re-setting.

**Figure 11.117 Error Occurrence in Normal Mode, Recovery in PWM Mode 2**

1 to 10 are the same as in figure 11.115.

11. Set PWM mode 2.
12. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized. If initialization is required, initialize in normal mode, then switch to PWM mode 2.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

Note: PWM mode 2 can only be set for channels 0 to 2, and therefore TOER setting is not necessary.

#### (4) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Phase Counting Mode

Figure 11.118 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in phase counting mode after re-setting.

**Figure 11.118 Error Occurrence in Normal Mode, Recovery in Phase Counting Mode**

1 to 10 are the same as in figure 11.115.

11. Set phase counting mode.
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

**Note:** Phase counting mode can only be set for channels 1 and 2, and therefore TOER setting is not necessary.

### (5) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.119 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in complementary PWM mode after re-setting.

**Figure 11.119 Error Occurrence in Normal Mode,  
Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.115.

11. Initialize the normal mode waveform generation section with TIOR.
12. Disable operation of the normal mode waveform generation section with TIOR.
13. Disable channel 3 and 4 output with TOER.
14. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
15. Set complementary PWM.
16. Enable channel 3 and 4 output with TOER.
17. Set MTU2 output with the PFC.
18. Operation is restarted by TSTR.

## (6) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 11.120 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in reset-synchronized PWM mode after re-setting.

**Figure 11.120 Error Occurrence in Normal Mode, Recovery in Reset-Synchronized PWM Mode**

1 to 13 are the same as in figure 11.115.

14. Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
15. Set reset-synchronized PWM.
16. Enable channel 3 and 4 output with TOER.
17. Set MTU2 output with the PFC.
18. Operation is restarted by TSTR.

## (7) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Normal Mode

Figure 11.121 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in normal mode after re-setting.

**Figure 11.121 Error Occurrence in PWM Mode 1, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Set PWM mode 1.
3. For channels 3 and 4, enable output with TOER before initializing the pins with TIOR.
4. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence. In PWM mode 1, the TIOC\*B side is not initialized.)
5. Set MTU2 output with the PFC.
6. The count operation is started by TSTR.
7. Output goes low on compare-match occurrence.
8. An error occurs.
9. Set port output with the PFC and output the inverse of the active level.
10. The count operation is stopped by TSTR.
11. Set normal mode.
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

### (8) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in PWM Mode 1

Figure 11.122 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.122 Error Occurrence in PWM Mode 1, Recovery in PWM Mode 1**

1 to 10 are the same as in figure 11.121.

11. Not necessary when restarting in PWM mode 1.
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC\*B side is not initialized.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

### (9) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in PWM Mode 2

Figure 11.123 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in PWM mode 2 after re-setting.

**Figure 11.123 Error Occurrence in PWM Mode 1, Recovery in PWM Mode 2**

1 to 10 are the same as in figure 11.121.

11. Set PWM mode 2.
12. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

Note: PWM mode 2 can only be set for channels 0 to 2, and therefore TOER setting is not necessary.

### (10) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Phase Counting Mode

Figure 11.124 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in phase counting mode after re-setting.

**Figure 11.124 Error Occurrence in PWM Mode 1, Recovery in Phase Counting Mode**

1 to 10 are the same as in figure 11.121.

11. Set phase counting mode.
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

**Note:** Phase counting mode can only be set for channels 1 and 2, and therefore TOER setting is not necessary.

### (11) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.125 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in complementary PWM mode after re-setting.

**Figure 11.125 Error Occurrence in PWM Mode 1,  
Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.121.

11. Set normal mode for initialization of the normal mode waveform generation section.
12. Initialize the PWM mode 1 waveform generation section with TIOR.
13. Disable operation of the PWM mode 1 waveform generation section with TIOR.
14. Disable channel 3 and 4 output with TOER.
15. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
16. Set complementary PWM.
17. Enable channel 3 and 4 output with TOER.
18. Set MTU2 output with the PFC.
19. Operation is restarted by TSTR.

## (12) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 11.126 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in reset-synchronized PWM mode after re-setting.

**Figure 11.126 Error Occurrence in PWM Mode 1, Recovery in Reset-Synchronized PWM Mode**

1 to 14 are the same as in figure 11.125.

15. Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
16. Set reset-synchronized PWM.
17. Enable channel 3 and 4 output with TOER.
18. Set MTU2 output with the PFC.
19. Operation is restarted by TSTR.

### (13) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in Normal Mode

Figure 11.127 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in normal mode after re-setting.

**Figure 11.127 Error Occurrence in PWM Mode 2, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Set PWM mode 2.
3. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence. In PWM mode 2, the cycle register pins are not initialized. In the example, TIOC \*A is the cycle register.)
4. Set MTU2 output with the PFC.
5. The count operation is started by TSTR.
6. Output goes low on compare-match occurrence.
7. An error occurs.
8. Set port output with the PFC and output the inverse of the active level.
9. The count operation is stopped by TSTR.
10. Set normal mode.
11. Initialize the pins with TIOR.
12. Set MTU2 output with the PFC.
13. Operation is restarted by TSTR.

### (14) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in PWM Mode 1

Figure 11.128 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.128 Error Occurrence in PWM Mode 2, Recovery in PWM Mode 1**

1 to 9 are the same as in figure 11.127.

10. Set PWM mode 1.

11. Initialize the pins with TIOR. (In PWM mode 1, the TIOC\*B side is not initialized.)

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

### (15) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in PWM Mode 2

Figure 11.129 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in PWM mode 2 after re-setting.

**Figure 11.129 Error Occurrence in PWM Mode 2, Recovery in PWM Mode 2**

1 to 9 are the same as in figure 11.127.

10. Not necessary when restarting in PWM mode 2.

11. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

### (16) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in Phase Counting Mode

Figure 11.130 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in phase counting mode after re-setting.

**Figure 11.130 Error Occurrence in PWM Mode 2, Recovery in Phase Counting Mode**

1 to 9 are the same as in figure 11.127.

10. Set phase counting mode.
11. Initialize the pins with TIOR.
12. Set MTU2 output with the PFC.
13. Operation is restarted by TSTR.

### (17) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in Normal Mode

Figure 11.131 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in normal mode after re-setting.

**Figure 11.131 Error Occurrence in Phase Counting Mode, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Set phase counting mode.
3. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence.)
4. Set MTU2 output with the PFC.
5. The count operation is started by TSTR.
6. Output goes low on compare-match occurrence.
7. An error occurs.
8. Set port output with the PFC and output the inverse of the active level.
9. The count operation is stopped by TSTR.
10. Set in normal mode.
11. Initialize the pins with TIOR.
12. Set MTU2 output with the PFC.
13. Operation is restarted by TSTR.

### (18) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 11.132 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.132 Error Occurrence in Phase Counting Mode, Recovery in PWM Mode 1**

1 to 9 are the same as in figure 11.131.

10. Set PWM mode 1.

11. Initialize the pins with TIOR. (In PWM mode 1, the TIOC \*B side is not initialized.)

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

### (19) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in PWM Mode 2

Figure 11.133 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in PWM mode 2 after re-setting.

**Figure 11.133 Error Occurrence in Phase Counting Mode, Recovery in PWM Mode 2**

1 to 9 are the same as in figure 11.131.

10. Set PWM mode 2.

11. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

## (20) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in Phase Counting Mode

Figure 11.134 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in phase counting mode after re-setting.

**Figure 11.134 Error Occurrence in Phase Counting Mode, Recovery in Phase Counting Mode**

1 to 9 are the same as in figure 11.131.

10. Not necessary when restarting in phase counting mode.

11. Initialize the pins with TIOR.

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

## (21) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Normal Mode

Figure 11.135 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in normal mode after re-setting.

**Figure 11.135 Error Occurrence in Complementary PWM Mode, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
3. Set complementary PWM.
4. Enable channel 3 and 4 output with TOER.
5. Set MTU2 output with the PFC.
6. The count operation is started by TSTR.
7. The complementary PWM waveform is output on compare-match occurrence.
8. An error occurs.
9. Set port output with the PFC and output the inverse of the active level.
10. The count operation is stopped by TSTR. (MTU2 output becomes the complementary PWM output initial value.)
11. Set normal mode. (MTU2 output goes low.)
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

## (22) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 11.136 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.136 Error Occurrence in Complementary PWM Mode, Recovery in PWM Mode 1**

1 to 10 are the same as in figure 11.135.

- Set PWM mode 1. (MTU2 output goes low.)
- Initialize the pins with TIOR. (In PWM mode 1, the TIOC \*B side is not initialized.)
- Set MTU2 output with the PFC.
- Operation is restarted by TSTR.

### (23) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.137 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in complementary PWM mode after re-setting (when operation is restarted using the cycle and duty settings at the time the counter was stopped).

**Figure 11.137 Error Occurrence in Complementary PWM Mode, Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.135.

11. Set MTU2 output with the PFC.
12. Operation is restarted by TSTR.
13. The complementary PWM waveform is output on compare-match occurrence.

Figure 11.138 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in complementary PWM mode after re-setting (when operation is restarted using completely new cycle and duty settings).

17. Operation is restarted by TSTR.

## (25) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 11.139 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in reset-synchronized PWM mode.

**Figure 11.139 Error Occurrence in Complementary PWM Mode, Recovery in Reset-Synchronized PWM Mode**

1 to 10 are the same as in figure 11.135.

11. Set normal mode. (MTU2 output goes low.)
12. Disable channel 3 and 4 output with TOER.
13. Select the reset-synchronized PWM mode output level and cyclic output enabling/disabling with TOCR.
14. Set reset-synchronized PWM.
15. Enable channel 3 and 4 output with TOER.
16. Set MTU2 output with the PFC.
17. Operation is restarted by TSTR.

## (26) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Normal Mode

Figure 11.140 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in normal mode after re-setting.

**Figure 11.140 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Normal Mode**

- After a reset, MTU2 output is low and ports are in the high-impedance state.
- Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
- Set reset-synchronized PWM.
- Enable channel 3 and 4 output with TOER.
- Set MTU2 output with the PFC.
- The count operation is started by TSTR.
- The reset-synchronized PWM waveform is output on compare-match occurrence.
- An error occurs.
- Set port output with the PFC and output the inverse of the active level.
- The count operation is stopped by TSTR. (MTU2 output becomes the reset-synchronized PWM output initial value.)
- Set normal mode. (MTU2 positive phase output is low, and negative phase output is high.)
- Initialize the pins with TIOR.
- Set MTU2 output with the PFC.
- Operation is restarted by TSTR.

## (27) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 11.141 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.141 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in PWM Mode 1**

1 to 10 are the same as in figure 11.140.

11. Set PWM mode 1. (MTU2 positive phase output is low, and negative phase output is high.)
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC \*B side is not initialized.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

## (28) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.142 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in complementary PWM mode after re-setting.

**Figure 11.142 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.140.

11. Disable channel 3 and 4 output with TOER.
12. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
13. Set complementary PWM. (The MTU2 cyclic output pin goes low.)
14. Enable channel 3 and 4 output with TOER.
15. Set MTU2 output with the PFC.
16. Operation is restarted by TSTR.

## (29) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 11.143 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in reset-synchronized PWM mode after re-setting.

**Figure 11.143 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Reset-Synchronized PWM Mode**

1 to 10 are the same as in figure 11.140.

11. Set MTU2 output with the PFC.
12. Operation is restarted by TSTR.
13. The reset-synchronized PWM waveform is output on compare-match occurrence.

## Section 12 Compare Match Timer (CMT)

This LSI has an on-chip compare match timer (CMT) consisting of a two-channel 16-bit timer. The CMT has a 16-bit counter, and can generate interrupts at set intervals.

### 12.1 Features

- Independent selection of four counter input clocks at two channels  
Any of four internal clocks ( $P\phi/8$ ,  $P\phi/32$ ,  $P\phi/128$ , and  $P\phi/512$ ) can be selected.
- Selection of DMA transfer request or interrupt request generation on compare match by DMAC setting
- When not in use, the CMT can be stopped by halting its clock supply to reduce power consumption.

Figure 12.1 shows a block diagram of CMT.

**Figure 12.1 Block Diagram of CMT**

## 12.2 Register Descriptions

The CMT has the following registers.

**Table 12.1 Register Configuration**

| Channel | Register Name                                 | Abbreviation | R/W | Initial Value | Address   | Access Size |
|---------|-----------------------------------------------|--------------|-----|---------------|-----------|-------------|
| Common  | Compare match timer start register            | CMSTR        | R/W | H'0000        | H'FFFE000 | 16          |
| 0       | Compare match timer control/status register_0 | CMCSR_0      | R/W | H'0000        | H'FFFE002 | 16          |
|         | Compare match counter_0                       | CMCNT_0      | R/W | H'0000        | H'FFFE004 | 8, 16       |
|         | Compare match constant register_0             | CMCOR_0      | R/W | H'FFFF        | H'FFFE006 | 8, 16       |
| 1       | Compare match timer control/status register_1 | CMCSR_1      | R/W | H'0000        | H'FFFE008 | 16          |
|         | Compare match counter_1                       | CMCNT_1      | R/W | H'0000        | H'FFFE00A | 8, 16       |
|         | Compare match constant register_1             | CMCOR_1      | R/W | H'FFFF        | H'FFFE00C | 8, 16       |

12.2.1 Compare Match Timer Start Register (CMSTR)

CMSTR is a 16-bit register that selects whether compare match counter (CMCNT) operates or is stopped.

|                |    |    |    |    |    |    |   |   |   |   |   |   |   |   |      |      |
|----------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|------|------|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1    | 0    |
|                | -  | -  | -  | -  | -  | -  | - | - | - | - | - | - | - | - | STR1 | STR0 |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0    | 0    |

### 12.2.2 Compare Match Timer Control/Status Register (CMCSR)

CMCSR is a 16-bit register that indicates compare match generation, enables or disables interrupts, and selects the counter input clock.

|                |    |    |    |    |    |    |   |   |        |      |   |   |   |   |          |     |
|----------------|----|----|----|----|----|----|---|---|--------|------|---|---|---|---|----------|-----|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7      | 6    | 5 | 4 | 3 | 2 | 1        | 0   |
|                | -  | -  | -  | -  | -  | -  | - | - | CMF    | CMIE | - | - | - | - | CKS[1:0] |     |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0      | 0    | 0 | 0 | 0 | 0 | 0        | 0   |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R/(W)* | R/W  | R | R | R | R | R/W      | R/W |

Note: \* Only 0 can be written to clear the flag after 1 is read.

| Bit     | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                               |

| Bit  | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|------|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1, 0 | CKS[1:0] | 00            | R/W | <p>Clock Select</p> <p>These bits select the clock to be input to CMCNT from four internal clocks obtained by dividing the peripheral clock (<math>P\phi</math>). When the STR bit in CMSTR is set to 1, CMCNT starts counting on the clock selected with bits CKS[1:0].</p> <p>00: <math>P\phi/8</math><br/>01: <math>P\phi/32</math><br/>10: <math>P\phi/128</math><br/>11: <math>P\phi/512</math></p> |

Note: \* Only 0 can be written to clear the flag after 1 is read.

### 12.2.3 Compare Match Counter (CMCNT)

CMCNT is a 16-bit register used as an up-counter. When the counter input clock is selected with bits CKS[1:0] in CMCSR, and the STR bit in CMSTR is set to 1, CMCNT starts counting using the selected clock. When the value in CMCNT and the value in compare match constant register (CMCOR) match, CMCNT is cleared to H'0000 and the CMF flag in CMCSR is set to 1.

CMCNT is initialized to H'0000 when the corresponding count start bit for a channel in the compare match timer start register (CMSTR) is cleared from 1 to 0.

### 12.2.4 Compare Match Constant Register (CMCOR)

CMCOR is a 16-bit register that sets the interval up to a compare match with CMCNT.

CMCOR is initialized to H'FFFF by a power-on reset or in software standby mode, but retains its previous value in module standby mode.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

## 12.3 Operation

### 12.3.1 Interval Count Operation

When an internal clock is selected with the CKS[1:0] bits in CMCSR and the STR bit in CMSTR is set to 1, CMCNT starts incrementing using the selected clock. When the values in CMCNT and CMCOR match, CMCNT is cleared to H'0000 and the CMF flag in CMCSR is set to 1. When the CMIE bit in CMCSR is set to 1 at this time, a compare match interrupt (CMI) is requested. CMCNT then starts counting up again from H'0000.

Figure 12.2 shows the operation of the compare match counter.

**Figure 12.2 Counter Operation**

### 12.3.2 CMCNT Count Timing

One of four clocks ( $P\phi/8$ ,  $P\phi/32$ ,  $P\phi/128$ , and  $P\phi/512$ ) obtained by dividing the peripheral clock ( $P\phi$ ) can be selected with the CKS1 and CKS0 bits in CMCSR. Figure 12.3 shows the timing.

**Figure 12.3 Count Timing**

## 12.4 Interrupts

### 12.4.1 Interrupt Sources and DMA Transfer Requests

The CMT has channels and each of them to which a different vector address is allocated has a compare match interrupt. When both the compare match flag (CMF) and the interrupt enable bit (CMIE) are set to 1, the corresponding interrupt request is output. When the interrupt is used to activate a CPU interrupt, the priority of channels can be changed by the interrupt controller settings. For details, see section 6, Interrupt Controller (INTC).

Clear the CMF bit to 0 by the user exception handling routine. If this operation is not carried out, another interrupt will be generated. The direct memory access controller (DMAC) can be set to be activated when a compare match interrupt is requested. In this case, an interrupt is not issued to the CPU. If the setting to activate the DMAC has not been made, an interrupt request is sent to the CPU. The CMF bit is automatically cleared to 0 when data is transferred by the DMAC.

### 12.4.2 Timing of Compare Match Flag Setting

When CMCOR and CMCNT match, a compare match signal is generated at the last state in which the values match (the timing when the CMCNT value is updated to H'0000) and the CMF bit in CMCSR is set to 1. That is, after a match between CMCOR and CMCNT, the compare match signal is not generated until the next CMCNT counter clock input. Figure 12.4 shows the timing of CMF bit setting.

**Figure 12.4 Timing of CMF Setting**

### 12.4.3 Timing of Compare Match Flag Clearing

The CMF bit in CMCSR is cleared by first, reading as 1 then writing to 0. However, in the case of the DMAC being activated, the CMF bit is automatically cleared to 0 when data is transferred by the DMAC.

## 12.5 Usage Notes

### 12.5.1 Conflict between Write and Compare-Match Processes of CMCNT

When the compare match signal is generated in the T2 cycle while writing to CMCNT, clearing CMCNT has priority over writing to it. In this case, CMCNT is not written to. Figure 12.5 shows the timing to clear the CMCNT counter.

**Figure 12.5 Conflict between Write and Compare Match Processes of CMCNT**

### 12.5.2 Conflict between Word-Write and Count-Up Processes of CMCNT

Even when the count-up occurs in the T2 cycle while writing to CMCNT in words, the writing has priority over the count-up. In this case, the count-up is not performed. Figure 12.6 shows the timing to write to CMCNT in words.

**Figure 12.6 Conflict between Word-Write and Count-Up Processes of CMCNT**

### 12.5.3 Conflict between Byte-Write and Count-Up Processes of CMCNT

Even when the count-up occurs in the T2 cycle while writing to CMCNT in bytes, the writing has priority over the count-up. In this case, the count-up is not performed. The byte data on the other side, which is not written to, is also not counted and the previous contents are retained.

Figure 12.7 shows the timing when the count-up occurs in the T2 cycle while writing to CMCNTH in bytes.

**Figure 12.7 Conflict between Byte-Write and Count-Up Processes of CMCNT**

### 12.5.4 Compare Match between CMCNT and CMCOR

Do not set the same value in CMCNT and CMCOR while CMCNT is not counting.

## Section 13 Watchdog Timer (WDT)

This LSI includes the watchdog timer (WDT), which externally outputs an overflow signal ( $\overline{\text{WDTOVF}}$ ) on overflow of the counter when the value of the counter has not been updated because of a system malfunction. The WDT can simultaneously generate an internal reset signal for the entire LSI.

The WDT is a single channel timer that counts up the clock oscillation settling period when the system leaves software standby mode or the temporary standby periods that occur when the clock frequency is changed. It can also be used as a general watchdog timer or interval timer.

### 13.1 Features

- Can be used to ensure the clock oscillation settling time  
The WDT is used in leaving software standby mode or the temporary standby periods that occur when the clock frequency is changed.
- Can switch between watchdog timer mode and interval timer mode.
- Outputs  $\overline{\text{WDTOVF}}$  signal in watchdog timer mode  
When the counter overflows in watchdog timer mode, the  $\overline{\text{WDTOVF}}$  signal is output externally. It is possible to select whether to reset the LSI internally when this happens. Either the power-on reset or manual reset signal can be selected as the internal reset type.
- Interrupt generation in interval timer mode  
An interval timer interrupt is generated when the counter overflows.
- Choice of eight counter input clocks  
Eight clocks ( $P\phi \times 1$  to  $P\phi \times 1/16384$ ) that are obtained by dividing the peripheral clock can be selected.

Figure 13.1 shows a block diagram of the WDT.

**Figure 13.1 Block Diagram of WDT**

## 13.2 Input/Output Pin

Table 13.1 shows the pin configuration of the WDT.

**Table 13.1 Pin Configuration**

| Pin Name                | Symbol                     | I/O    | Function                                                   |
|-------------------------|----------------------------|--------|------------------------------------------------------------|
| Watchdog timer overflow | $\overline{\text{WDTOVF}}$ | Output | Outputs the counter overflow signal in watchdog timer mode |

## 13.3 Register Descriptions

The WDT has the following registers.

**Table 13.2 Register Configuration**

| Register Name                          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|----------------------------------------|--------------|-----|---------------|------------|-------------|
| Watchdog timer counter                 | WTCNT        | R/W | H'00          | H'FFFE0002 | 16*         |
| Watchdog timer control/status register | WTCSR        | R/W | H'18          | H'FFFE0000 | 16*         |
| Watchdog reset control/status register | WRCSR        | R/W | H'1F          | H'FFFE0004 | 16*         |

Note: \* For the access size, see section 13.3.4, Notes on Register Access.

### 13.3.1 Watchdog Timer Counter (WTCNT)

WTCNT is an 8-bit readable/writable register that is incremented by cycles of the selected clock signal. When an overflow occurs, it generates a watchdog timer overflow signal ( $\overline{\text{WDTOVF}}$ ) in watchdog timer mode and an interrupt in interval timer mode.

Use word access to write to WTCNT, writing H'5A in the upper byte. Use byte access to read from WTCNT.

Note: The method for writing to WTCNT differs from that for other registers to prevent erroneous writes. See section 13.3.4, Notes on Register Access, for details.

|                |                      |                      |                      |                      |                      |                      |                      |                      |
|----------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| Bit:           | 7                    | 6                    | 5                    | 4                    | 3                    | 2                    | 1                    | 0                    |
|                | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> |
| Initial value: | 0                    | 0                    | 0                    | 0                    | 0                    | 0                    | 0                    | 0                    |
| R/W:           | R/W                  | R/W                  | R/W                  | R/W                  | R/W                  | R/W                  | R/W                  | R/W                  |

13.3.2 Watchdog Timer Control/Status Register (WTCSR)

WTCSR is an 8-bit readable/writable register composed of bits to select the clock used for the count, overflow flags, and timer enable bit.

When used to count the clock oscillation settling time for canceling software standby mode, it retains its value after counter overflow.

Use word access to write to WTCSR, writing H'A5 in the upper byte. Use byte access to read from WTCSR.

Note: The method for writing to WTCSR differs from that for other registers to prevent erroneous writes. See section 13.3.4, Notes on Register Access, for details.

| 110:        | $1/4096 \times P\phi$  | 32 ms          |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |             |                |      |                  |             |      |                     |             |      |                      |        |      |                      |        |      |                      |        |      |                       |        |      |                       |       |      |                        |        |
| 111:        | $1/16384 \times P\phi$ | 128 ms         |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |             |                |      |                  |             |      |                     |             |      |                      |        |      |                      |        |      |                      |        |      |                       |        |      |                       |       |      |                        |        |

### 13.3.3 Watchdog Reset Control/Status Register (WRCSR)

WRCSR is an 8-bit readable/writable register that controls output of the internal reset signal generated by watchdog timer counter (WTCNT) overflow.

**Note:** The method for writing to WRCSR differs from that for other registers to prevent erroneous writes. See section 13.3.4, Notes on Register Access, for details.

### 13.3.4 Notes on Register Access

The watchdog timer counter (WTCNT), watchdog timer control/status register (WTCSR), and watchdog reset control/status register (WRCSR) are more difficult to write to than other registers. The procedures for reading or writing to these registers are given below.

#### (1) Writing to WTCNT and WTCSR

These registers must be written by a word transfer instruction. They cannot be written by a byte or longword transfer instruction.

When writing to WTCNT, set the upper byte to H'5A and transfer the lower byte as the write data, as shown in figure 13.2. When writing to WTCSR, set the upper byte to H'A5 and transfer the lower byte as the write data. This transfer procedure writes the lower byte data to WTCNT or WTCSR.

**Figure 13.2 Writing to WTCNT and WTCSR**

(2) Writing to WRCSR

WRCSR must be written by a word access to address H'FFFE0004. It cannot be written by byte transfer or longword transfer instructions.

Procedures for writing 0 to WOVF (bit 7) and for writing to RSTE (bit 6) and RSTS (bit 5) are different, as shown in figure 13.3.

To write 0 to the WOVF bit, the write data must be H'A5 in the upper byte and H'00 in the lower byte. This clears the WOVF bit to 0. The RSTE and RSTS bits are not affected. To write to the RSTE and RSTS bits, the upper byte must be H'5A and the lower byte must be the write data. The values of bits 6 and 5 of the lower byte are transferred to the RSTE and RSTS bits, respectively. The WOVF bit is not affected.

Figure 13.3 Writing to WRCSR

(3) Reading from WTCNT, WTCSR, and WRCSR

WTCNT, WTCSR, and WRCSR are read in a method similar to other registers. WTCSR is allocated to address H'FFFE0000, WTCNT to address H'FFFE0002, and WRCSR to address H'FFFE0004. Byte transfer instructions must be used for reading from these registers.

## 13.4 WDT Usage

### 13.4.1 Canceling Software Standby Mode

The WDT can be used to cancel software standby mode with an interrupt such as an NMI interrupt. The procedure is described below. (The WDT does not operate when resets are used for canceling, so keep the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin low until clock oscillation settles.)

1. Before making a transition to software standby mode, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
2. Set the type of count clock used in the CKS[2:0] bits in WTCSR and the initial value of the counter in WTCNT. These values should ensure that the time till count overflow is longer than the clock oscillation settling time.
3. After setting the STBY bit of the standby control register (STBCR: see section 28, Power-Down Modes) to 1, the execution of a SLEEP instruction puts the system in software standby mode and clock operation then stops.
4. The WDT starts counting by detecting the edge change of the NMI signal.
5. When the WDT count overflows, the CPG starts supplying the clock and this LSI resumes operation. The WOVF flag in WRCSR is not set when this happens.

### 13.4.2 Changing the Frequency

To change the frequency used by the PLL, use the WDT. When changing the frequency only by switching the divider, do not use the WDT.

1. Before changing the frequency, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
2. Set the type of count clock used in the CKS[2:0] bits in WTCSR and the initial value of the counter in WTCNT. These values should ensure that the time till count overflow is longer than the clock oscillation settling time. However, the WDT counts up using the clock after the setting.
3. When the frequency control register (FRQCR) is written to, this LSI stops temporarily. The WDT starts counting.
4. When the WDT count overflows, the CPG resumes supplying the clock and this LSI resumes operation. The WOVF flag in WRCSR is not set when this happens.
5. The counter stops at the value of H'00.
6. Before changing WTCNT after execution of the frequency change instruction, always confirm that the value of WTCNT is H'00 by reading from WTCNT.

### 13.4.3 Using Watchdog Timer Mode

1. Set the  $\overline{WT/IT}$  bit in WTCSR to 1, the type of count clock in the CKS[2:0] bits in WTCSR, whether this LSI is to be reset internally or not in the RSTE bit in WRCSR, the reset type if it is generated in the RSTS bit in WRCSR, and the initial value of the counter in WTCNT.
2. Set the TME bit in WTCSR to 1 to start the count in watchdog timer mode.
3. While operating in watchdog timer mode, rewrite the counter periodically to H'00 to prevent the counter from overflowing.
4. When the counter overflows, the WDT sets the WOVF flag in WRCSR to 1, and the  $\overline{WDTOVF}$  signal is output externally (figure 13.4). The  $\overline{WDTOVF}$  signal can be used to reset the system. The  $\overline{WDTOVF}$  signal is output for  $64 \times P\phi$  clock cycles.
5. If the RSTE bit in WRCSR is set to 1, a signal to reset the inside of this LSI can be generated simultaneously with the  $\overline{WDTOVF}$  signal. Either power-on reset or manual reset can be selected for this interrupt by the RSTS bit in WRCSR. The internal reset signal is output for  $128 \times P\phi$  clock cycles.
6. When a WDT overflow reset is generated simultaneously with a reset input on the  $\overline{RES}$  pin, the  $\overline{RES}$  pin reset takes priority, and the WOVF bit in WRCSR is cleared to 0.

Figure 13.4 Operation in Watchdog Timer Mode

### 13.4.4 Using Interval Timer Mode

When operating in interval timer mode, interval timer interrupts are generated at every overflow of the counter. This enables interrupts to be generated at set periods.

1. Clear the  $\overline{WT/IT}$  bit in WTCSR to 0, set the type of count clock in the CKS[2:0] bits in WTCSR, and set the initial value of the counter in WTCNT.
2. Set the TME bit in WTCSR to 1 to start the count in interval timer mode.
3. When the counter overflows, the WDT sets the IOVF bit in WTCSR to 1 and an interval timer interrupt request is sent to the INTC. The counter then resumes counting.

**Figure 13.5 Operation in Interval Timer Mode**

## 13.5 Usage Notes

Pay attention to the following points when using the WDT in either the interval timer or watchdog timer mode.

### 13.5.1 Timer Variation

After timer operation has started, the period from the power-on reset point to the first count up timing of WTCNT varies depending on the time period that is set by the TME bit of WTCSR. The shortest such time period is thus one cycle of the peripheral clock,  $P\phi$ , while the longest is the result of frequency division according to the value in the CKS[2:0] bits. The timing of subsequent incrementation is in accord with the selected frequency division ratio. Accordingly, this time difference is referred to as timer variation.

This also applies to the timing of the first incrementation after WTCNT has been written to during timer operation.

### 13.5.2 Prohibition against Setting H'FF to WTCNT

When the value in WTCNT reaches H'FF, the WDT assumes that an overflow has occurred. Accordingly, when H'FF is set in WTCNT, an interval timer interrupt or WDT reset will occur immediately, regardless of the current clock selection by the CKS[2:0] bits.

### 13.5.3 Interval Timer Overflow Flag

When the value in WTCNT is H'FF, the IOVF flag in WTCSR cannot be cleared.

Only clear the IOVF flag when the value in WTCNT has either become H'00 or been changed to a value other than H'FF.

### 13.5.4 System Reset by $\overline{\text{WDTOVF}}$ Signal

If the  $\overline{\text{WDTOVF}}$  signal is input to the  $\overline{\text{RES}}$  pin of this LSI, this LSI cannot be initialized correctly.

Avoid input of the  $\overline{\text{WDTOVF}}$  signal to the  $\overline{\text{RES}}$  pin of this LSI through glue logic circuits. To reset the entire system with the  $\overline{\text{WDTOVF}}$  signal, use the circuit shown in figure 13.6.

**Figure 13.6 Example of System Reset Circuit Using  $\overline{\text{WDTOVF}}$  Signal**

### 13.5.5 Manual Reset in Watchdog Timer Mode

When a manual reset occurs in watchdog timer mode, the bus cycle is continued. If a manual reset occurs while the bus is released or during DMAC burst transfer, manual reset exception handling will be pended until the CPU acquires the bus mastership.

### 13.5.6 Internal Reset in Watchdog Timer Mode

When an internal reset is generated by an overflow of the watchdog timer counter (WTCNT) in watchdog timer mode, the watchdog reset control/status register (WRCSR) is not initialized and the WOVF bit is set to 1. When the value of the WOVF bit is 1, no internal reset is generated when a WTCNT overflow occurs.

## Section 14 Realtime Clock (RTC)

This LSI has a realtime clock (RTC) with its own 32.768-kHz crystal oscillator.

### 14.1 Features

- Clock and calendar functions (BCD format): Seconds, minutes, hours, date, day of the week, month, and year
- 1-Hz to 64-Hz timer (binary format)  
64-Hz counter indicates the state of the RTC divider circuit between 64 Hz and 1 Hz
- Start/stop function
- 30-second adjust function
- Alarm interrupt: Frame comparison of seconds, minutes, hours, date, day of the week, month, and year can be used as conditions for the alarm interrupt
- Periodic interrupts: the interrupt cycle may be 1/256 second, 1/64 second, 1/16 second, 1/4 second, 1/2 second, 1 second, or 2 seconds
- Carry interrupt: a carry interrupt indicates when a carry occurs during a counter read
- Automatic leap year adjustment

Figure 14.1 shows the block diagram of RTC.

**Figure 14.1 RTC Block Diagram**

## 14.2 Input/Output Pin

Table 14.1 shows the RTC pin configuration.

**Table 14.1 Pin Configuration**

| Pin Name                             | Symbol | I/O    | Description                                                                                                        |
|--------------------------------------|--------|--------|--------------------------------------------------------------------------------------------------------------------|
| RTC crystal resonator/external clock | RTC_X1 | Input  | Connects to a 32.768 kHz crystal resonator for the RTC. Alternately, an external clock may be input on pin RTC_X1. |
|                                      | RTC_X2 | Output |                                                                                                                    |

## 14.3 Register Descriptions

The RTC has the following registers.

**Table 14.2 Register Configuration**

| Register Name              | Abbreviation | R/W | Initial Value | Address     | Access Size |
|----------------------------|--------------|-----|---------------|-------------|-------------|
| 64-Hz counter              | R64CNT       | R   | H'xx          | H'FFFF 2000 | 8           |
| Second counter             | RSECCNT      | R/W | H'xx          | H'FFFF 2002 | 8           |
| Minute counter             | RMINCNT      | R/W | H'xx          | H'FFFF 2004 | 8           |
| Hour counter               | RHRCNT       | R/W | H'xx          | H'FFFF 2006 | 8           |
| Day of week counter        | RWKCNT       | R/W | H'xx          | H'FFFF 2008 | 8           |
| Date counter               | RDAYCNT      | R/W | H'xx          | H'FFFF 200A | 8           |
| Month counter              | RMONCNT      | R/W | H'xx          | H'FFFF 200C | 8           |
| Year counter               | RYRCNT       | R/W | H'xxxx        | H'FFFF 200E | 16          |
| Second alarm register      | RSECAR       | R/W | H'xx          | H'FFFF 2010 | 8           |
| Minute alarm register      | RMINAR       | R/W | H'xx          | H'FFFF 2012 | 8           |
| Hour alarm register        | RHRAR        | R/W | H'xx          | H'FFFF 2014 | 8           |
| Day of week alarm register | RWKAR        | R/W | H'xx          | H'FFFF 2016 | 8           |
| Date alarm register        | RDAYAR       | R/W | H'xx          | H'FFFF 2018 | 8           |
| Month alarm register       | RMONAR       | R/W | H'xx          | H'FFFF 201A | 8           |
| Year alarm register        | RYRAR        | R/W | H'xxxx        | H'FFFF 2020 | 16          |
| RTC control register 1     | RCR1         | R/W | H'00          | H'FFFF 201C | 8           |
| RTC control register 2     | RCR2         | R/W | H'09          | H'FFFF 201E | 8           |
| RTC control register 3     | RCR3         | R/W | H'00          | H'FFFF 2024 | 8           |

### 14.3.1 64-Hz Counter (R64CNT)

R64CNT indicates the state of the divider circuit between 64 Hz and 1 Hz.

Reading this register, when carry from 128-Hz divider stage is generated, sets the CF bit in the RTC control register 1 (RCR1) to 1 so that the carrying and reading 64 Hz counter are performed at the same time is indicated. In this case, the R64CNT should be read again after writing 0 to the CF bit in RCR1 since the read value is not valid.

After the RESET bit or ADJ bit in the RTC control register 2 (RCR2) is set to 1, the RTC divider circuit is initialized and R64CNT is initialized.

|                |   |     |     |     |     |      |      |      |
|----------------|---|-----|-----|-----|-----|------|------|------|
| Bit:           | 7 | 6   | 5   | 4   | 3   | 2    | 1    | 0    |
|                | - | 1Hz | 2Hz | 4Hz | 8Hz | 16Hz | 32Hz | 64Hz |
| Initial value: | 0 | -   | -   | -   | -   | -    | -    | -    |
| R/W:           | R | R   | R   | R   | R   | R    | R    | R    |

| Bit | Bit Name | Initial Value | R/W | Description                                                                   |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------|
| 7   | —        | 0             | R   | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 6   | 1 Hz     | Undefined     | R   | Indicate the state of the divider circuit between 64 Hz and 1 Hz.             |
| 5   | 2 Hz     | Undefined     | R   |                                                                               |
| 4   | 4 Hz     | Undefined     | R   |                                                                               |
| 3   | 8 Hz     | Undefined     | R   |                                                                               |
| 2   | 16 Hz    | Undefined     | R   |                                                                               |
| 1   | 32 Hz    | Undefined     | R   |                                                                               |
| 0   | 64 Hz    | Undefined     | R   |                                                                               |

### 14.3.2 Second Counter (RSECCNT)

RSECCNT is used for setting/counting in the BCD-coded second section. The count operation is performed by a carry for each second of the 64-Hz counter.

The assignable range is from 00 through 59 (practically in BCD), otherwise operation errors occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

|                |   |            |     |     |          |     |     |     |
|----------------|---|------------|-----|-----|----------|-----|-----|-----|
| Bit:           | 7 | 6          | 5   | 4   | 3        | 2   | 1   | 0   |
|                | - | 10 seconds |     |     | 1 second |     |     |     |
| Initial value: | 0 | -          | -   | -   | -        | -   | -   | -   |
| R/W:           | R | R/W        | R/W | R/W | R/W      | R/W | R/W | R/W |

| Bit    | Bit Name   | Initial Value | R/W | Description                                                                                                                          |
|--------|------------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------|
| 7      | —          | 0             | R   | Reserved<br>This bit is always read as 0. The write value should always be 0.                                                        |
| 6 to 4 | 10 seconds | Undefined     | R/W | Counting Ten's Position of Seconds<br>Counts on 0 to 5 for 60-seconds counting.                                                      |
| 3 to 0 | 1 second   | Undefined     | R/W | Counting One's Position of Seconds<br>Counts on 0 to 9 once per second. When a carry is generated, 1 is added to the ten's position. |

14.3.3 Minute Counter (RMINCNT)

RMINCNT is used for setting/counting in the BCD-coded minute section. The count operation is performed by a carry for each minute of the second counter.

The assignable range is from 00 through 59 (practically in BCD), otherwise operation errors occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

|                |   |            |     |     |          |     |     |     |
|----------------|---|------------|-----|-----|----------|-----|-----|-----|
| Bit:           | 7 | 6          | 5   | 4   | 3        | 2   | 1   | 0   |
|                | - | 10 minutes |     |     | 1 minute |     |     |     |
| Initial value: | 0 | -          | -   | -   | -        | -   | -   | -   |
| R/W:           | R | R/W        | R/W | R/W | R/W      | R/W | R/W | R/W |

| Bit    | Bit Name   | Initial Value | R/W | Description                                                                                                                          |
|--------|------------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------|
| 7      | —          | 0             | R   | Reserved<br>This bit is always read as 0.The write value should always be 0.                                                         |
| 6 to 4 | 10 minutes | Undefined     | R/W | Counting Ten's Position of Minutes<br>Counts on 0 to 5 for 60-minutes counting.                                                      |
| 3 to 0 | 1 minute   | Undefined     | R/W | Counting One's Position of Minutes<br>Counts on 0 to 9 once per second. When a carry is generated, 1 is added to the ten's position. |

### 14.3.4 Hour Counter (RHRCNT)

RHRCNT is used for setting/counting in the BCD-coded hour section. The count operation is performed by a carry for each 1 hour of the minute counter.

The assignable range is from 00 through 23 (practically in BCD), otherwise operation errors occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

|                |   |   |          |     |        |     |     |     |
|----------------|---|---|----------|-----|--------|-----|-----|-----|
| Bit:           | 7 | 6 | 5        | 4   | 3      | 2   | 1   | 0   |
|                | - | - | 10 hours |     | 1 hour |     |     |     |
| Initial value: | 0 | 0 | -        | -   | -      | -   | -   | -   |
| R/W:           | R | R | R/W      | R/W | R/W    | R/W | R/W | R/W |

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                      |
|--------|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------|
| 7, 6   | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                 |
| 5, 4   | 10 hours | Undefined     | R/W | Counting Ten's Position of Hours<br>Counts on 0 to 2 for ten's position of hours.                                                |
| 3 to 0 | 1 hour   | Undefined     | R/W | Counting One's Position of Hours<br>Counts on 0 to 9 once per hour. When a carry is generated, 1 is added to the ten's position. |

14.3.5 Day of Week Counter (RWKCNT)

RWKCNT is used for setting/counting day of week section. The count operation is performed by a carry for each day of the date counter.

The assignable range is from 0 through 6 (practically in BCD), otherwise operation errors occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

|                |   |   |   |   |   |     |     |     |
|----------------|---|---|---|---|---|-----|-----|-----|

### 14.3.6 Date Counter (RDAYCNT)

RDAYCNT is used for setting/counting in the BCD-coded date section. The count operation is performed by a carry for each day of the hour counter.

The assignable range is from 01 through 31 (practically in BCD), otherwise operation errors occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

The range of date changes with each month and in leap years. Confirm the correct setting. Leap years are recognized by dividing the year counter (RYRCNT) values by 400, 100, and 4 and obtaining a fractional result of 0.

|                |   |   |         |     |       |     |     |     |
|----------------|---|---|---------|-----|-------|-----|-----|-----|
| Bit:           | 7 | 6 | 5       | 4   | 3     | 2   | 1   | 0   |

14.3.7 Month Counter (RMONCNT)

RMONCNT is used for setting/counting in the BCD-coded month section. The count operation is performed by a carry for each month of the date counter.

The assignable range is from 01 through 12 (practically in BCD), otherwise operation errors occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

|                |   |   |   |           |         |     |     |     |

### 14.3.8 Year Counter (RYRCNT)

RYRCNT is used for setting/counting in the BCD-coded year section. The count operation is performed by a carry for each year of the month counter.

The assignable range is from 0000 through 9999 (practically in BCD), otherwise operation errors occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

| Bit      | Bit Name   | Initial Value | R/W | Description                           |
|----------|------------|---------------|-----|---------------------------------------|
| 15 to 12 | 1000 years | Undefined     | R/W | Counting Thousand's Position of Years |
| 11 to 8  | 100 years  | Undefined     | R/W | Counting Hundred's Position of Years  |
| 7 to 4   | 10 years   | Undefined     | R/W | Counting Ten's Position of Years      |
| 3 to 0   | 1 year     | Undefined     | R/W | Counting One's Position of Years      |

14.3.9 Second Alarm Register (RSECAR)

RSECAR is an alarm register corresponding to the BCD coded second counter RSECCNT of the RTC. When the ENB bit is set to 1, a comparison with the RSECCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 00 through 59 + ENB bits (practically in BCD), otherwise operation errors occur.

| Bit    | Bit Name   | Initial Value | R/W | Description                                                                  |
|--------|------------|---------------|-----|------------------------------------------------------------------------------|
| 7      | ENB        | 0             | R/W | When this bit is set to 1, a comparison with the RSECCNT value is performed. |
| 6 to 4 | 10 seconds | Undefined     | R/W | Ten's position of seconds setting value                                      |
| 3 to 0 | 1 second   | Undefined     | R/W | One's position of seconds setting value                                      |

14.3.10 Minute Alarm Register (RMINAR)

RMINAR is an alarm register corresponding to the minute counter RMINCNT. When the ENB bit is set to 1, a comparison with the RMINCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 00 through 59 + ENB bits (practically in BCD), otherwise operation errors occur.

| Bit    | Bit Name   | Initial Value | R/W | Description                                                                  |
|--------|------------|---------------|-----|------------------------------------------------------------------------------|
| 7      | ENB        | 0             | R/W | When this bit is set to 1, a comparison with the RMINCNT value is performed. |
| 6 to 4 | 10 minutes | Undefined     | R/W | Ten's position of minutes setting value                                      |
| 3 to 0 | 1 minute   | Undefined     | R/W | One's position of minutes setting value                                      |

14.3.11 Hour Alarm Register (RHRAR)

RHRAR is an alarm register corresponding to the BCD coded hour counter RHRCNT of the RTC. When the ENB bit is set to 1, a comparison with the RHRCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 00 through 23 + ENB bits (practically in BCD), otherwise operation errors occur.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                   |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------|
| 7      | ENB      | 0             | R/W | When this bit is set to 1, a comparison with the RHRCNT value is performed.   |
| 6      | —        | 0             | R   | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 5, 4   | 10 hours | Undefined     | R/W | Ten's position of hours setting value                                         |
| 3 to 0 | 1 hour   | Undefined     | R/W | One's position of hours setting value                                         |

### 14.3.12 Day of Week Alarm Register (RWKAR)

RWKAR is an alarm register corresponding to the BCD coded day of week counter RWKCNT. When the ENB bit is set to 1, a comparison with the RWKCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 0 through 6 + ENB bits (practically in BCD), otherwise operation errors occur.

|                |     |   |   |   |   |     |     |     |
|----------------|-----|---|---|---|---|-----|-----|-----|
| Bit:           | 7   | 6 | 5 | 4 | 3 | 2   | 1   | 0   |

14.3.13 Date Alarm Register (RDAYAR)

RDAYAR is an alarm register corresponding to the BCD coded date counter RDAYCNT. When the ENB bit is set to 1, a comparison with the RDAYCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 01 through 31 + ENB bits (practically in BCD), otherwise operation errors occur.

|                |     |   |         |       |     |     |     |     |
|----------------|-----|---|---------|-------|-----|-----|-----|-----|
| Bit:           | 7   | 6 | 5       | 4     | 3   | 2   | 1   | 0   |
|                | ENB | - | 10 days | 1 day |     |     |     |     |
| Initial value: | 0   | 0 | -       | -     | -   | -   | -   | -   |
| R/W:           | R/W | R | R/W     | R/W   | R/W | R/W | R/W | R/W |

| Bit    | Bit Name | Initial Value | R/W | Description                                                                   |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------|
| 7      | ENB      | 0             | R/W | When this bit is set to 1, a comparison with the RDAYCNT value is performed.  |
| 6      | —        | 0             | R   | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 5, 4   | 10 days  | Undefined     | R/W | Ten's position of dates setting value                                         |
| 3 to 0 | 1 day    | Undefined     | R/W | One's position of dates setting value                                         |

### 14.3.14 Month Alarm Register (RMONAR)

RMONAR is an alarm register corresponding to the BCD coded month counter RMONCNT. When the ENB bit is set to 1, a comparison with the RMONCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 01 through 12 + ENB bits (practically in BCD), otherwise operation errors occur.

|                |     |   |   |           |         |     |     |     |
|----------------|-----|---|---|-----------|---------|-----|-----|-----|
| Bit:           | 7   | 6 | 5 | 4         | 3       | 2   | 1   | 0   |

| Initial value: | 0   | 0 | 0 | -         | -       | -   | -   | -   |
| R/W:           | R/W | R | R | R/W       | R/W     | R/W | R/W | R/W |

| Bit    | Bit Name | Initial Value | R/W | Description                                                                      |
|--------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 7      | ENB      | 0             | R/W | When this bit is set to 1, a comparison with the RMONCNT value is performed.     |
| 6, 5   | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 4      | 10 month | Undefined     | R/W | Ten's position of months setting value                                           |
| 3 to 0 | 1 month  | Undefined     | R/W | One's position of months setting value                                           |

14.3.15 Year Alarm Register (RYRAR)

RYRAR is an alarm register corresponding to the year counter RYRCNT. The assignable range is from 0000 through 9999 (practically in BCD), otherwise operation errors occur.

| Bit      | Bit Name   | Initial Value | R/W | Description                                |
|----------|------------|---------------|-----|--------------------------------------------|
| 15 to 12 | 1000 years | Undefined     | R/W | Thousand's position of years setting value |
| 11 to 8  | 100 years  | Undefined     | R/W | Hundred's position of years setting value  |
| 7 to 4   | 10 years   | Undefined     | R/W | Ten's position of years setting value      |
| 3 to 0   | 1 year     | Undefined     | R/W | One's position of years setting value      |

### 14.3.16 RTC Control Register 1 (RCR1)

RCR1 is a register that affects carry flags and alarm flags. It also selects whether to generate interrupts for each flag.

The CF flag remains undefined until the divider circuit is reset (the RESET and ADJ bits in RCR2 are set to 1). When using the CF flag, make sure to reset the divider circuit beforehand.

|                |     |   |   |     |     |   |   |     |
|----------------|-----|---|---|-----|-----|---|---|-----|
| Bit:           | 7   | 6 | 5 | 4   | 3   | 2 | 1 | 0   |
|                | CF  | - | - | CIE | AIE | - | - | AF  |
| Initial value: | -   | 0 | 0 | 0   | 0   | 0 | 0 | 0   |
| R/W:           | R/W | R | R | R/W | R/W | R | R | R/W |

| Bit  | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 14.3.17 RTC Control Register 2 (RCR2)

RCR2 is a register for periodic interrupt control, 30-second adjustment ADJ, divider circuit RESET, and RTC count control.

RCR2 is initialized by a power-on reset or in deep standby mode. Bits other than the RTCEN and START bits are initialized by a manual reset.

### 14.3.18 RTC Control Register 3 (RCR3)

When the ENB bit is set to 1, RCR3 performs a comparison with the RYRCNT. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

## 14.4 Operation

RTC usage is shown below.

### 14.4.1 Initial Settings of Registers after Power-On

All the registers should be set after the power is turned on.

### 14.4.2 Setting Time

Figure 14.2 shows how to set the time when the clock is stopped.

**Figure 14.2 Setting Time**

### 14.4.3 Reading Time

Figure 14.3 shows how to read the time.

**Figure 14.3 Reading Time**

If a carry occurs while reading the time, the correct time will not be obtained, so it must be read again. Part (a) in figure 14.3 shows the method of reading the time without using interrupts; part

(b) in figure 14.3 shows the method using carry interrupts. To keep programming simple, method (a) should normally be used.

#### 14.4.4 Alarm Function

Figure 14.4 shows how to use the alarm function.

**Figure 14.4 Using Alarm Function**

Alarms can be generated using seconds, minutes, hours, day of the week, date, month, year, or any combination of these. Set the ENB bit in the register on which the alarm is placed to 1, and then set the alarm time in the lower bits. Clear the ENB bit in the register on which the alarm is not placed to 0.

When the clock and alarm times match, 1 is set in the AF bit in RCR1. Alarm detection can be checked by reading this bit, but normally it is done by interrupt. If 1 is set in the AIE bit in RCR1, an interrupt is generated when an alarm occurs.

The alarm flag is set when the clock and alarm times match. However, the alarm flag can be cleared by writing 0.

## 14.5 Usage Notes

### 14.5.1 Register Writing during RTC Count

The following RTC registers cannot be written to during an RTC count (while bit 0 = 1 in RCR2).

RSECCNT, RMINCNT, RHRCNT, RDAYCNT, RWKCNT, RMONCNT, RYRCNT

The RTC count must be stopped before writing to any of the above registers.

### 14.5.2 Use of Real-time Clock (RTC) Periodic Interrupts

The method of using the periodic interrupt function is shown in figure 14.5.

A periodic interrupt can be generated periodically at the interval set by bits PES2 to PES0 in RCR2. When the time set by bits PES2 to PES0 has elapsed, the PEF is set to 1.

The PEF is cleared to 0 upon periodic interrupt generation or when bits PES2 to PES0 are set. Periodic interrupt generation can be confirmed by reading this bit, but normally the interrupt function is used.

**Figure 14.5 Using Periodic Interrupt Function**

### 14.5.3 Transition to Standby Mode after Setting Register

When a transition to standby mode is made after registers in the RTC are set, sometimes counting is not performed correctly. In case the registers are set, be sure to make a transition to standby mode after performing one dummy read the register.

#### 14.5.4 Notes on Register Read and Write Operations

- Follow the procedure shown in figure 14.2 when reading data after writing to counter registers such as the second counter register. In this case, it is necessary to write to all the counters, from second to year, in succession. Do not read the counter registers during the write processing shown as (2) in figure 14.2.
- After writing to the RCR2 register, perform two dummy reads before reading data. The register contents from before the write are returned by the two dummy reads, and the third read returns the register contents reflecting the write.
- Registers other than the above can be read immediately after a write and the written value is reflected.

## Section 15 Serial Communication Interface with FIFO (SCIF)

This LSI has a four-channel serial communication interface with FIFO (SCIF) that supports both asynchronous and clock synchronous serial communication. It also has 16-stage FIFO registers for both transmission and reception independently for each channel that enable this LSI to perform efficient high-speed continuous communication.

### 15.1 Features

- Asynchronous serial communication:
  - Serial data communication is performed by start-stop in character units. The SCIF can communicate with a universal asynchronous receiver/transmitter (UART), an asynchronous communication interface adapter (ACIA), or any other communications chip that employs a standard asynchronous serial system. There are eight selectable serial data communication formats.
  - Data length: 7 or 8 bits
  - Stop bit length: 1 or 2 bits
  - Parity: Even, odd, or none
  - Receive error detection: Parity, framing, and overrun errors
  - Break detection: Break is detected when a framing error is followed by at least one frame at the space 0 level (low level). It is also detected by reading the RxD level directly from the serial port register when a framing error occurs.
- Clock synchronous serial communication:
  - Serial data communication is synchronized with a clock signal. The SCIF can communicate with other chips having a clock synchronous communication function. There is one serial data communication format.
  - Data length: 8 bits
  - Receive error detection: Overrun errors
- Full duplex communication: The transmitting and receiving sections are independent, so the SCIF can transmit and receive simultaneously. Both sections use 16-stage FIFO buffering, so high-speed continuous data transfer is possible in both the transmit and receive directions.
- On-chip baud rate generator with selectable bit rates
- Internal or external transmit/receive clock source: From either baud rate generator (internal) or SCK pin (external)

- Four types of interrupts: Transmit-FIFO-data-empty interrupt, break interrupt, receive-FIFO-data-full interrupt, and receive-error interrupts are requested independently.
- When the SCIF is not in use, it can be stopped by halting the clock supplied to it, saving power.
- In asynchronous mode, on-chip modem control functions ( $\overline{\text{RTS}}$  and  $\overline{\text{CTS}}$ ) (only channel 3).
- The quantity of data in the transmit and receive FIFO data registers and the number of receive errors of the receive data in the receive FIFO data register can be ascertained.
- A time-out error (DR) can be detected when receiving in asynchronous mode.
- In asynchronous mode, the base clock frequency can be either 16 or 8 times the bit rate.
- When an internal clock is selected as a clock source and the SCK pin is used as an input pin in asynchronous mode, either normal mode or double-speed mode can be selected for the baud rate generator.

Figure 15.1 shows a block diagram of the SCIF. Note that channels 0 to 2 have no  $\overline{\text{CTS}}$  and  $\overline{\text{RTS}}$  pins.

**Figure 15.1 Block Diagram of SCIF**

## 15.2 Input/Output Pins

Table 15.1 shows the pin configuration of the SCIF.

**Table 15.1 Pin Configuration**

| Channel | Pin Name            | Symbol                   | I/O    | Function             |
|---------|---------------------|--------------------------|--------|----------------------|
| 0 to 3  | Serial clock pins   | SCK0 to SCK3             | I/O    | Clock I/O            |
|         | Receive data pins   | RxD0 to RxD3             | Input  | Receive data input   |
|         | Transmit data pins  | TxD0 to TxD3             | Output | Transmit data output |
| 3       | Request to send pin | $\overline{\text{RTS3}}$ | I/O    | Request to send      |
|         | Clear to send pin   | $\overline{\text{CTS3}}$ | I/O    | Clear to send        |

## 15.3 Register Descriptions

The SCIF has the following registers.

**Table 15.2 Register Configuration**

| Channel | Register Name                    | Abbreviation | R/W                 | Initial Value | Address    | Access Size |

- Notes: 1. Only 0 can be written to clear the flag. Bits 15 to 8, 3, and 2 are read-only bits that cannot be modified.
2. Only 0 can be written to clear the flag. Bits 15 to 1 are read-only bits that cannot be modified.

### 15.3.1 Receive Shift Register (SCRSR)

SCRSR receives serial data. Data input at the RxD pin is loaded into SCRSR in the order received, LSB (bit 0) first, converting the data to parallel form. When one byte has been received, it is automatically transferred to the receive FIFO data register (SCFRDR).

The CPU cannot read or write to SCRSR directly.

|                |             |             |             |             |             |             |             |             |
|----------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| Bit:           | 7           | 6           | 5           | 4           | 3           | 2           | 1           | 0           |

| R/W:           | -           | -           | -           | -           | -           | -           | -           | -           |

### 15.3.2 Receive FIFO Data Register (SCFRDR)

SCFRDR is a 16-byte FIFO register that stores serial receive data. The SCIF completes the reception of one byte of serial data by moving the received data from the receive shift register (SCRSR) into SCFRDR for storage. Continuous reception is possible until 16 bytes are stored. The CPU can read but not write to SCFRDR. If data is read when there is no receive data in the SCFRDR, the value is undefined.

When SCFRDR is full of receive data, subsequent serial data is lost.

|                |             |             |             |             |             |             |             |             |
|----------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| Bit:           | 7           | 6           | 5           | 4           | 3           | 2           | 1           | 0           |

| R/W:           | R           | R           | R           | R           | R           | R           | R           | R           |

### 15.3.3 Transmit Shift Register (SCTSR)

SCTSR transmits serial data. The SCIF loads transmit data from the transmit FIFO data register (SCFTDR) into SCTSR, then transmits the data serially from the TxD pin, LSB (bit 0) first. After transmitting one data byte, the SCIF automatically loads the next transmit data from SCFTDR into SCTSR and starts transmitting again.

The CPU cannot read from or write to SCTSR directly.

|                |                      |                      |                      |                      |                      |                      |                      |                      |

### 15.3.4 Transmit FIFO Data Register (SCFTDR)

SCFTDR is a 16-byte FIFO register that stores data for serial transmission. When the SCIF detects that the transmit shift register (SCTSR) is empty, it moves transmit data written in the SCFTDR into SCTSR and starts serial transmission. Continuous serial transmission is performed until there is no transmit data left in SCFTDR. The CPU can write to SCFTDR at all times.

When SCFTDR is full of transmit data (16 bytes), no more data can be written. If writing of new data is attempted, the data is ignored.

|                |                      |                      |                      |                      |                      |                      |                      |                      |
|----------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| Bit:           | 7                    | 6                    | 5                    | 4                    | 3                    | 2                    | 1                    | 0                    |

| Initial value: | -                    | -                    | -                    | -                    | -                    | -                    | -                    | -                    |
| R/W:           | W                    | W                    | W                    | W                    | W                    | W                    | W                    | W                    |

### 15.3.5 Serial Mode Register (SCSMR)

SCSMR specifies the SCIF serial communication format and selects the clock source for the baud rate generator.

The CPU can always read from and write to SCSMR.

### 15.3.6 Serial Control Register (SCSCR)

SCSCR operates the SCIF transmitter/receiver, enables/disables interrupt requests, and selects the transmit/receive clock source. The CPU can always read and write to SCSCR.

### 15.3.7 Serial Status Register (SCFSR)

SCFSR is a 16-bit register. The upper 8 bits indicate the number of receive errors in the receive FIFO data register, and the lower 8 bits indicate the status flag indicating SCIF operating state.

The CPU can always read and write to SCFSR, but cannot write 1 to the status flags (ER, TEND, TDFE, BRK, RDF, and DR). These flags can be cleared to 0 only if they have first been read (after being set to 1). The PER flag (bits 15 to 12 and bit 2) and the FER flag (bits 11 to 8 and bit 3) are read-only bits that cannot be written.

The value indicated by bits 11 to 8 after the ER bit in SCFSR is set, represents the number of framing errors in SCFRDR. When framing errors have occurred in all 16-byte receive data in SCFRDR, FER[3:0] shows 0000.</p>                               |

Note: \* Only 0 can be written to clear the flag after 1 is read.

### 15.3.8 Bit Rate Register (SCBRR)

SCBRR is an 8-bit register that is used with the CKS1 and CKS0 bits in the serial mode register (SCSMR) and the BGDM and ABCS bits in the serial extension mode register (SCEMR) to determine the serial transmit/receive bit rate.

The CPU can always read and write to SCBRR. SCBRR is initialized to H'FF by a power-on reset. Each channel has independent baud rate generator control, so different values can be set in three channels.

The SCBRR setting is calculated as follows:

- Asynchronous mode:

When baud rate generator operates in normal mode (when the BGDM bit of SCEMR is 0):

$$N = \frac{P\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1 \quad (\text{Operation on a base clock with a frequency of 16 times the bit rate})$$

$$N = \frac{P\phi}{32 \times 2^{2n-1} \times B} \times 10^6 - 1 \quad (\text{Operation on a base clock with a frequency of 8 times the bit rate})$$

When baud rate generator operates in double speed mode (when the BGDM bit of SCEMR is 1):

$$N = \frac{P\phi}{32 \times 2^{2n-1} \times B} \times 10^6 - 1 \quad (\text{Operation on a base clock with a frequency of 16 times the bit rate})$$

$$N = \frac{P\phi}{16 \times 2^{2n-1} \times B} \times 10^6 - 1 \quad (\text{Operation on a base clock with a frequency of 8 times the bit rate})$$

- Clock synchronous mode:

$$N = \frac{P\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bits/s)

N: SCBRR setting for baud rate generator ( $0 \leq N \leq 255$ )  
(The setting must satisfy the electrical characteristics.)

$P\phi$ : Operating frequency for peripheral modules (MHz)

n: Baud rate generator clock source ( $n = 0, 1, 2, 3$ ) (for the clock sources and values of n, see table 15.3.)

**Table 15.3 SCSMR Settings**

| n | Clock Source | SCSMR Settings |        |
|---|--------------|----------------|--------|
|   |              | CKS[1]         | CKS[0] |
| 0 | $P\phi$      | 0              | 0      |
| 1 | $P\phi/4$    | 0              | 1      |
| 2 | $P\phi/16$   | 1              | 0      |
| 3 | $P\phi/64$   | 1              | 1      |

The bit rate error in asynchronous mode is given by the following formula:

When baud rate generator operates in normal mode (the BGDM bit of SCEMR is 0):

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100 \quad \text{(Operation on a base clock with a frequency of 16 times the bit rate)}$$

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 32 \times 2^{2n-1}} - 1 \right\} \times 100 \quad \text{(Operation on a base clock with a frequency of 8 times the bit rate)}$$

When baud rate generator operates in double speed mode (the BGDM bit of SCEMR is 1):

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 32 \times 2^{2n-1}} - 1 \right\} \times 100 \quad \text{(Operation on a base clock with a frequency of 16 times the bit rate)}$$

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 16 \times 2^{2n-1}} - 1 \right\} \times 100 \quad \text{(Operation on a base clock with a frequency of 8 times the bit rate)}$$

Table 15.4 lists the sample SCBRR settings in asynchronous mode in which a base clock frequency is 16 times the bit rate (the ABCS bit in SCEMR is 0) and the baud rate generator operates in normal mode (the BGDM bit in SCEMR is 1), and table 15.5 lists the sample SCBRR settings in clock synchronous mode.

**Table 15.4 Bit Rates and SCBRR Settings (Asynchronous Mode, BGDM = 0, ABCS = 0) (1)**

[Legend]

Blank: No setting possible, or the electrical characteristics of the SH7203 cannot be satisfied regardless of the device being communicated with.

—: Setting possible, but error occurs

Table 15.6 indicates the maximum bit rates in asynchronous mode when the baud rate generator is used. Table 15.7 lists the maximum bit rates in asynchronous mode when the external clock input is used. Table 15.8 lists the maximum bit rates in clock synchronous mode when the external clock input is used (when  $t_{\text{Seyc}} = 12t_{\text{pcyc}}^*$ ).

Note: \* Make sure that the electrical characteristics of this LSI and that of a connected LSI are satisfied.

**Table 15.6 Maximum Bit Rates for Various Frequencies with Baud Rate Generator (Asynchronous Mode)**

| P $\phi$ (MHz) | Settings |      |   |   | Maximum Bit Rate (bits/s) |

### 15.3.9 FIFO Control Register (SCFCR)

SCFCR resets the quantity of data in the transmit and receive FIFO data registers, sets the trigger data quantity, and contains an enable bit for loop-back testing. SCFCR can always be read and written to by the CPU.

### 15.3.10 FIFO Data Count Set Register (SCFDR)

SCFDR is a 16-bit register which indicates the quantity of data stored in the transmit FIFO data register (SCFTDR) and the receive FIFO data register (SCFRDR).

It indicates the quantity of transmit data in SCFTDR with the upper 8 bits, and the quantity of receive data in SCFRDR with the lower 8 bits. SCFDR can always be read by the CPU.

| 4 to 0   | R[4:0]   | 00000         | R   | R4 to R0 bits indicate the quantity of receive data stored in SCFRDR. H'00 means no receive data, and H'10 means that SCFRDR full of receive data.              |

### 15.3.11 Serial Port Register (SCSPTR)

SCSPTR controls input/output and data of pins multiplexed to SCIF function. Bits 7 and 6 can control input/output data of  $\overline{\text{RTS}}$  pin. Bits 5 and 4 can control input/output data of  $\overline{\text{CTS}}$  pin. Bits 3 and 2 can control input/output data of SCK pin. Bits 1 and 0 can input data from Rx pin and output data to Tx pin, so they control break of serial transmitting/receiving.

The CPU can always read and write to SCSPTR.

### 15.3.12 Line Status Register (SCLSR)

The CPU can always read or write to SCLSR, but cannot write 1 to the ORER flag. This flag can be cleared to 0 only if it has first been read (after being set to 1).

Clearing the RE bit to 0 in SCSCR does not affect the ORER bit, which retains its previous value.</li> <li>2. The receive FIFO data register (SCFRDR) retains the data before an overrun error has occurred, and the next received data is discarded. When the ORER bit is set to 1, the SCIF cannot continue the next serial reception.</li> </ol> |

### 15.3.13 Serial Extension Mode Register (SCEMR)

The CPU can always read from or write to SCEMR. Setting the BGDM bit in this register to 1 allows the baud rate generator in the SCIF operates in double-speed mode when asynchronous mode is selected (by setting the  $\overline{C/A}$  bit in SCSMR to 0) and an internal clock is selected as a clock source and the SCK pin is set as an input pin (by setting the CKE[1:0] bits in SCSCR to 00).

## 15.4 Operation

### 15.4.1 Overview

For serial communication, the SCIF has an asynchronous mode in which characters are synchronized individually, and a clock synchronous mode in which communication is synchronized with clock pulses.

The SCIF has a 16-stage FIFO buffer for both transmission and receptions, reducing the overhead of the CPU, and enabling continuous high-speed communication. Furthermore, channel 3 has  $\overline{\text{RTS}}$  and  $\overline{\text{CTS}}$  signals to be used as modem control signals.

The transmission format is selected in the serial mode register (SCSMR), as shown in table 15.9. The SCIF clock source is selected by the combination of the CKE1 and CKE0 bits in the serial control register (SCSCR), as shown in table 15.10.

#### (1) Asynchronous Mode

- Data length is selectable: 7 or 8 bits
- Parity bit is selectable. So is the stop bit length (1 or 2 bits). The combination of the preceding selections constitutes the communication format and character length.
- In receiving, it is possible to detect framing errors, parity errors, receive FIFO data full, overrun errors, receive data ready, and breaks.
- The number of stored data bytes is indicated for both the transmit and receive FIFO registers.
- An internal or external clock can be selected as the SCIF clock source.
  - When an internal clock is selected, the SCIF operates using the clock of on-chip baud rate generator.
  - When an external clock is selected, the external clock input must have a frequency 16 or 8 times the bit rate. (The on-chip baud rate generator is not used.)

**(2) Clock Synchronous Mode**

- The transmission/reception format has a fixed 8-bit data length.
- In receiving, it is possible to detect overrun errors (ORER).
- An internal or external clock can be selected as the SCIF clock source.
  - When an internal clock is selected, the SCIF operates using the clock of the on-chip baud rate generator, and outputs this clock to external devices as the synchronous clock.
  - When an external clock is selected, the SCIF operates on the input external synchronous clock not using the on-chip baud rate generator.

[Legend]

x: Don't care

Note: When using the baud rate generator in double-speed mode (BGMD = 1), select asynchronous mode by setting the C/A bit to 0, and select an internal clock as a clock source and the SCK pin is not used (the CKE[1:0] bits set to 00).

### 15.4.2 Operation in Asynchronous Mode

In asynchronous mode, each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections of the SCIF are independent, so full duplex communication is possible. The transmitter and receiver are 16-byte FIFO buffered, so data can be written and read while transmitting and receiving are in progress, enabling continuous transmitting and receiving.

Figure 15.2 shows the general format of asynchronous serial communication.

In asynchronous serial communication, the communication line is normally held in the mark (high) state. The SCIF monitors the line and starts serial communication when the line goes to the space (low) state, indicating a start bit. One serial character consists of a start bit (low), data (LSB first), parity bit (high or low), and stop bit (high), in that order.

When receiving in asynchronous mode, the SCIF synchronizes at the falling edge of the start bit. The SCIF samples each data bit on the eighth or fourth pulse of a clock with a frequency 16 or 8 times the bit rate. Receive data is latched at the center of each bit.

**Figure 15.2 Example of Data Format in Asynchronous Communication  
(8-Bit Data with Parity and Two Stop Bits)**

**(1) Transmit/Receive Formats**

Table 15.11 lists the eight communication formats that can be selected in asynchronous mode. The format is selected by settings in the serial mode register (SCSMR).

**Table 15.11 Serial Communication Formats (Asynchronous Mode)**

| SCSMR Bits |    |      | Serial Transmit/Receive Format and Frame Length |            |   |   |   |   |   |      |      |      |      |    |
|------------|----|------|-------------------------------------------------|------------|---|---|---|---|---|------|------|------|------|----|
| CHR        | PE | STOP | 1                                               | 2          | 3 | 4 | 5 | 6 | 7 | 8    | 9    | 10   | 11   | 12 |
| 0          | 0  | 0    | START                                           | 8-bit data |   |   |   |   |   |      | STOP |      |      |    |

P: Parity bit

## (2) Clock

An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCIF transmit/receive clock. The clock source is selected by the  $C/\bar{A}$  bit in the serial mode register (SCSMR) and the CKE1 and CKE0 bits in the serial control register (SCSCR). For clock source selection, refer to table 15.10, SCSMR and SCSCR Settings and SCIF Clock Source Selection.

When an external clock is input at the SCK pin, it must have a frequency equal to 16 or 8 times the desired bit rate.

When the SCIF operates on an internal clock, it can output a clock signal on the SCK pin. The frequency of this output clock is 16 or 8 times the desired bit rate.

## (3) Transmitting and Receiving Data

- SCIF Initialization (Asynchronous Mode)

Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCIF as follows.

When changing the operation mode or the communication format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 initializes the transmit shift register (SCTSR). Clearing TE and RE to 0, however, does not initialize the serial status register (SCFSR), transmit FIFO data register (SCFTDR), or receive FIFO data register (SCFRDR), which retain their previous contents. Clear TE to 0 after all transmit data has been transmitted and the TEND flag in the SCFSR is set. The TE bit can be cleared to 0 during transmission, but the transmit data goes to the Mark state after the bit is cleared to 0. Set the TFRST bit in SCFCR to 1 and reset SCFTDR before TE is set again to start transmission.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCIF operation becomes unreliable if the clock is stopped.

Figure 15.3 shows a sample flowchart for initializing the SCIF.

**Figure 15.3 Sample Flowchart for SCIF Initialization**

- Transmitting Serial Data (Asynchronous Mode)

Figure 15.4 shows a sample flowchart for serial transmission.

Use the following procedure for serial data transmission after enabling the SCIF for transmission.

**Figure 15.4 Sample Flowchart for Transmitting Serial Data**

In serial transmission, the SCIF operates as described below.

1. When data is written into the transmit FIFO data register (SCFTDR), the SCIF transfers the data from SCFTDR to the transmit shift register (SCTSR) and starts transmitting. Confirm that the TDFE flag in the serial status register (SCFSR) is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is (16 – transmit trigger setting).
2. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR falls below the transmit trigger number set in the FIFO control register (SCFCR), the TDFE flag is set. If the TIE bit in the serial control register (SCSR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

The serial transmit data is sent from the TxD pin in the following order.

- A. Start bit: One-bit 0 is output.
  - B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
  - C. Parity bit: One parity bit (even or odd parity) is output. (A format in which a parity bit is not output can also be selected.)
  - D. Stop bit(s): One or two 1 bits (stop bits) are output.
  - E. Mark state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The SCIF checks the SCFTDR transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCFTDR to SCTSR, the stop bit is sent, and then serial transmission of the next frame is started.

Figure 15.5 shows an example of the operation for transmission.

**Figure 15.5 Example of Transmit Operation  
(8-Bit Data, Parity, 1 Stop Bit)**

- When modem control is enabled in channel 3, transmission can be stopped and restarted in accordance with the  $\overline{\text{CTS}}$  input value. When  $\overline{\text{CTS}}$  is set to 1, if transmission is in progress, the line goes to the mark state after transmission of one frame. When  $\overline{\text{CTS}}$  is set to 0, the next transmit data is output starting from the start bit.

Figure 15.6 shows an example of the operation when modem control is used.

**Figure 15.6 Example of Operation Using Modem Control ( $\overline{\text{CTS}}$ )**

- Receiving Serial Data (Asynchronous Mode)

Figures 15.7 and 15.8 show sample flowcharts for serial reception.

Use the following procedure for serial data reception after enabling the SCIF for reception.

**Figure 15.7 Sample Flowchart for Receiving Serial Data**

- Whether a framing error or parity error has occurred in the receive data that is to be read from the receive FIFO data register (SCFRDR) can be ascertained from the FER and PER bits in the serial status register (SCFSR).
- When a break signal is received, receive data is not transferred to SCFRDR while the BRK flag is set. However, note that the last data in SCFRDR is H'00, and the break data in which a framing error occurred is stored.

**Figure 15.8 Sample Flowchart for Receiving Serial Data (cont)**

In serial reception, the SCIF operates as described below.

1. The SCIF monitors the transmission line, and if a 0 start bit is detected, performs internal synchronization and starts reception.
2. The received data is stored in SCRSR in LSB-to-MSB order.
3. The parity bit and stop bit are received.

After receiving these bits, the SCIF carries out the following checks.

- A. Stop bit check: The SCIF checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
- B. The SCIF checks whether receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.
- C. Overrun check: The SCIF checks that the ORER flag is 0, indicating that the overrun error has not occurred.
- D. Break check: The SCIF checks that the BRK flag is 0, indicating that the break state is not set.

If all the above checks are passed, the receive data is stored in SCFRDR.

Note: When a parity error or a framing error occurs, reception is not suspended.

4. If the RIE bit in SCSCR is set to 1 when the RDF or DR flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated. If the RIE bit or the REIE bit in SCSCR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated. If the RIE bit or the REIE bit in SCSCR is set to 1 when the BRK or ORER flag changes to 1, a break reception interrupt (BRI) request is generated.

Figure 15.9 shows an example of the operation for reception.

**Figure 15.9 Example of SCIF Receive Operation  
(8-Bit Data, Parity, 1 Stop Bit)**

- When modem control is enabled in channel 3, the  $\overline{\text{RTS}}$  signal is output when SCFRDR is empty. When  $\overline{\text{RTS}}$  is 0, reception is possible. When  $\overline{\text{RTS}}$  is 1, this indicates that SCFRDR exceeds the number set for the RTS output active trigger.

Figure 15.10 shows an example of the operation when modem control is used.

**Figure 15.10 Example of Operation Using Modem Control ( $\overline{\text{RTS}}$ )**

### 15.4.3 Operation in Clock Synchronous Mode

In clock synchronous mode, the SCIF transmits and receives data in synchronization with clock pulses. This mode is suitable for high-speed serial communication.

The SCIF transmitter and receiver are independent, so full-duplex communication is possible while sharing the same clock. The transmitter and receiver are also 16-byte FIFO buffered, so continuous transmitting or receiving is possible by reading or writing data while transmitting or receiving is in progress.

Figure 15.11 shows the general format in clock synchronous serial communication.

**Figure 15.11 Data Format in Clock Synchronous Communication**

In clock synchronous serial communication, each data bit is output on the communication line from one falling edge of the serial clock to the next. Data is guaranteed valid at the rising edge of the serial clock.

In each character, the serial data bits are transmitted in order from the LSB (first) to the MSB (last). After output of the MSB, the communication line remains in the state of the MSB.

In clock synchronous mode, the SCIF receives data by synchronizing with the rising edge of the serial clock.

### (1) Transmit/Receive Formats

The data length is fixed at eight bits. No parity bit can be added.

### (2) Clock

An internal clock generated by the on-chip baud rate generator by the setting of the C/A bit in SCSMR and CKE[1:0] in SCSCR, or an external clock input from the SCK pin can be selected as the SCIF transmit/receive clock.

When the SCIF operates on an internal clock, it outputs the clock signal at the SCK pin. Eight clock pulses are output per transmitted or received character. When the SCIF is not transmitting or receiving, the clock signal remains in the high state. When only receiving, the clock signal outputs while the RE bit of SCSCR is 1 and the number of data in receive FIFO is more than the receive FIFO data trigger number.

### (3) Transmitting and Receiving Data

- SCIF Initialization (Clock Synchronous Mode)

Before transmitting, receiving, or changing the mode or communication format, the software must clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCIF. Clearing TE to 0 initializes the transmit shift register (SCTSR). Clearing RE to 0, however, does not initialize the RDF, PER, FER, and ORER flags and receive data register (SCRDR), which retain their previous contents.

Figure 15.12 shows a sample flowchart for initializing the SCIF.

**Figure 15.12 Sample Flowchart for SCIF Initialization**

- Transmitting Serial Data (Clock Synchronous Mode)

Figure 15.13 shows a sample flowchart for transmitting serial data.

Use the following procedure for serial data transmission after enabling the SCIF for transmission.

**Figure 15.13 Sample Flowchart for Transmitting Serial Data**

In serial transmission, the SCIF operates as described below.

1. When data is written into the transmit FIFO data register (SCFTDR), the SCIF transfers the data from SCFTDR to the transmit shift register (SCTSR) and starts transmitting. Confirm that the TDFE flag in the serial status register (SCFSR) is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is (16 – transmit trigger setting).
2. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR falls below the transmit trigger number set in the FIFO control register (SCFCR), the TDFE flag is set. If the TIE bit in the serial control register (SCSR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

If clock output mode is selected, the SCIF outputs eight synchronous clock pulses. If an external clock source is selected, the SCIF outputs data in synchronization with the input clock. Data is output from the TxD pin in order from the LSB (bit 0) to the MSB (bit 7).

3. The SCIF checks the SCFTDR transmit data at the timing for sending the MSB (bit 7). If data is present, the data is transferred from SCFTDR to SCTSR, and then serial transmission of the next frame is started. If there is no data, the TxD pin holds the state after the TEND flag in SCFSR is set to 1 and the MSB (bit 7) is sent.
4. After the end of serial transmission, the SCK pin is held in the high state.

Figure 15.14 shows an example of SCIF transmit operation.

**Figure 15.14 Example of SCIF Transmit Operation**

- Receiving Serial Data (Clock Synchronous Mode)

Figures 15.15 and 15.16 show sample flowcharts for receiving serial data. When switching from asynchronous mode to clock synchronous mode without SCIF initialization, make sure that ORER, PER, and FER are cleared to 0.

**Figure 15.15 Sample Flowchart for Receiving Serial Data (1)**

**Figure 15.16 Sample Flowchart for Receiving Serial Data (2)**

In serial reception, the SCIF operates as described below.

1. The SCIF synchronizes with serial clock input or output and starts the reception.
2. Receive data is shifted into SCRSR in order from the LSB to the MSB. After receiving the data, the SCIF checks the receive data can be loaded from SCRSR into SCFRDR or not. If this check is passed, the RDF flag is set to 1 and the SCIF stores the received data in SCFRDR. If the check is not passed (overrun error is detected), further reception is prevented.
3. After setting RDF to 1, if the receive FIFO data full interrupt enable bit (RIE) is set to 1 in SCSCR, the SCIF requests a receive-data-full interrupt (RXI). If the ORER bit is set to 1 and the receive-data-full interrupt enable bit (RIE) or the receive error interrupt enable bit (REIE) in SCSCR is also set to 1, the SCIF requests a break interrupt (BRI).

Figure 15.17 shows an example of SCIF receive operation.

**Figure 15.17 Example of SCIF Receive Operation**

- Transmitting and Receiving Serial Data Simultaneously (Clock Synchronous Mode)

Figure 15.18 shows a sample flowchart for transmitting and receiving serial data simultaneously.

Use the following procedure for the simultaneous transmission/reception of serial data, after enabling the SCIF for transmission/reception.

**Figure 15.18 Sample Flowchart for Transmitting/Receiving Serial Data**

## 15.5 SCIF Interrupts

The SCIF has four interrupt sources: transmit-FIFO-data-empty (TXI), receive-error (ERI), receive FIFO data full (RXI), and break (BRI).

Table 15.12 shows the interrupt sources and their order of priority. The interrupt sources are enabled or disabled by means of the TIE, RIE, and REIE bits in SCSCR. A separate interrupt request is sent to the interrupt controller for each of these interrupt sources.

When a TXI request is enabled by the TIE bit and the TDFE flag in the serial status register (SCFSR) is set to 1, a TXI interrupt request is generated. The DMAC can be activated and data transfer performed by this TXI interrupt request. At this time, an interrupt request is not sent to the CPU.

When an RXI request is enabled by the RIE bit and the RDF flag or the DR flag in SCFSR is set to 1, an RXI interrupt request is generated. The DMAC can be activated and data transfer performed by this RXI interrupt request. At this time, an interrupt request is not sent to the CPU. The RXI interrupt request caused by the DR flag is generated only in asynchronous mode.

When the RIE bit is set to 0 and the REIE bit is set to 1, the SCIF requests an ERI or BRI interrupt without requesting an RXI interrupt.

The TXI indicates that transmit data can be written, and the RXI indicates that there is receive data in SCFRDR.

**Table 15.12 SCIF Interrupt Sources**

| Interrupt Source | Description                                                            | DMAC Activation | Priority on Reset Release                                                           |
|------------------|------------------------------------------------------------------------|-----------------|-------------------------------------------------------------------------------------|
| BRI              | Interrupt initiated by break (BRK) or overrun error (ORER)             | Not possible    |  |
| ERI              | Interrupt initiated by receive error (ER)                              | Not possible    |                                                                                     |
| RXI              | Interrupt initiated by receive FIFO data full (RDF) or data ready (DR) | Possible        |                                                                                     |
| TXI              | Interrupt initiated by transmit FIFO data empty (TDFE)                 | Possible        |                                                                                     |

## 15.6 Usage Notes

Note the following when using the SCIF.

### 15.6.1 SCFTDR Writing and TDFE Flag

The TDFE flag in the serial status register (SCFSR) is set when the number of transmit data bytes written in the transmit FIFO data register (SCFTDR) has fallen below the transmit trigger number set by bits TTRG[1:0] in the FIFO control register (SCFCR). After the TDFE flag is set, transmit data up to the number of empty bytes in SCFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in SCFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being read as 1 and cleared to 0. TDFE flag clearing should therefore be carried out when SCFTDR contains more than the transmit trigger number of transmit data bytes.

The number of transmit data bytes in SCFTDR can be found from the upper 8 bits of the FIFO data count register (SCFDR).

### 15.6.2 SCFRDR Reading and RDF Flag

The RDF flag in the serial status register (SCFSR) is set when the number of receive data bytes in the receive FIFO data register (SCFRDR) has become equal to or greater than the receive trigger number set by bits RTRG[1:0] in the FIFO control register (SCFCR). After RDF flag is set, receive data equivalent to the trigger number can be read from SCFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCFRDR exceeds the trigger number, the RDF flag will be set to 1 again if it is cleared to 0. The RDF flag should therefore be cleared to 0 after being read as 1 after reading the number of the received data in the receive FIFO data register (SCFRDR) which is less than the trigger number.

The number of receive data bytes in SCFRDR can be found from the lower 8 bits of the FIFO data count register (SCFDR).

### 15.6.3 Restriction on DMAC Usage

When the DMAC writes data to SCFTDR due to a TXI interrupt request, the state of the TEND flag becomes undefined. Therefore, the TEND flag should not be used as the transfer end flag in such a case.

### 15.6.4 Break Detection and Processing

Break signals can be detected by reading the RxD pin directly when a framing error (FER) is detected. In the break state the input from the RxD pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set.

Note that, although transfer of receive data to SCFRDR is halted in the break state, the SCIF receiver continues to operate.

### 15.6.5 Sending a Break Signal

The I/O condition and level of the TxD pin are determined by the SPB2IO and SPB2DT bits in the serial port register (SCSPTR). This feature can be used to send a break signal.

Until TE bit is set to 1 (enabling transmission) after initializing, the TxD pin does not work. During the period, mark status is performed by the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (high level output).

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (designating low level), then clear the TE bit to 0 (halting transmission). When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, and 0 is output from the TxD pin.

### 15.6.6 Receive Data Sampling Timing and Receive Margin (Asynchronous Mode)

The SCIF operates on a base clock with a frequency 16 or 8 times the bit rate. In reception, the SCIF synchronizes internally with the fall of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth or fourth base clock pulse. When the SCIF operates on a base clock with a frequency 16 times the bit rate, the receive data is sampled at the timing shown in figure 15.19.

**Figure 15.19 Receive Data Sampling Timing in Asynchronous Mode  
(Operation on a Base Clock with a Frequency 16 Times the Bit Rate)**

The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

**Equation 1:**

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 \%$$

Where: M: Receive margin (%)

N: Ratio of clock frequency to bit rate (N = 16 or 8)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation 1, if F = 0, D = 0.5 and N = 16, the receive margin is 46.875%, as given by equation 2.

**Equation 2:**

When D = 0.5 and F = 0:

$$\begin{aligned} M &= (0.5 - 1/(2 \times 16)) \times 100\% \\ &= 46.875\% \end{aligned}$$

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

### 15.6.7 Selection of Base Clock in Asynchronous Mode

In this LSI, when asynchronous mode is selected, the base clock frequency within a bit period can be set to the frequency 16 or 8 times the bit rate by setting the ABCS bit in SCEMR.

Note that, however, if the base clock frequency 8 times the bit rate is used, receive margin is decreased as calculated using equation 1 in section 15.6.6, Receive Data Sampling Timing and Receive Margin (Asynchronous Mode).

If the desired bit rate can be set simply by setting SCBRR and the CKS1 and CKS0 bits in SCSMR, it is recommended to use the base clock frequency within a bit period 16 times the bit rate (by setting the ABCS bit in SCEMR to 0). If an internal clock is selected as a clock source and the SCK pin is not used, the bit rate can be increased without decreasing receive margin by selecting double-speed mode for the baud rate generator (setting the BGDM bit in SCEMR to 1).

## Section 16 Synchronous Serial Communication Unit (SSU)

This LSI has two synchronous serial communication unit (SSU) channels. The SSU has master mode in which this LSI outputs clocks as a master device for synchronous serial communication and slave mode in which clocks are input from an external device for synchronous serial communication. Synchronous serial communication can be performed with devices having different clock polarity and clock phase.

### 16.1 Features

- Choice of SSU mode and clock synchronous mode
- Choice of master mode and slave mode
- Choice of standard mode and bidirectional mode
- Synchronous serial communication with devices with different clock polarity and clock phase
- Choice of 8/16/32-bit width of transmit/receive data
- Full-duplex communication capability

The shift register is incorporated, enabling transmission and reception to be executed simultaneously.

- Consecutive serial communication
- Choice of LSB-first or MSB-first transfer
- Choice of a clock source  
P $\phi$ /4, P $\phi$ /8, P $\phi$ /16, P $\phi$ /32, P $\phi$ /64, P $\phi$ /128, P $\phi$ /256, or an external clock
- Five interrupt sources

Transmit end, transmit data register empty, receive data full, overrun error, and conflict error.

The direct memory access controller (DMAC) can be activated by a transmit data register empty request or a receive data full request to transfer data.

- Module standby mode can be set  
To reduce power consumption, the operation of the SSU can be suspended by stopping the clock supply to the SSU.

Figure 16.1 shows a block diagram of the SSU.

**Figure 16.1 Block Diagram of SSU**

## 16.2 Input/Output Pins

Table 16.1 shows the SSU pin configuration.

**Table 16.1 Pin Configuration**

| Channel | Symbol       | I/O | Function                     |
|---------|--------------|-----|------------------------------|
| 0, 1    | SSCK0, SSCK1 | I/O | SSU clock input/output       |
|         | SSI0, SSI1   | I/O | SSU data input/output        |
|         | SSO0, SSO1   | I/O | SSU data input/output        |
|         | SCS0, SCS1   | I/O | SSU chip select input/output |

## 16.3 Register Descriptions

The SSU has the following registers. For details on the addresses of these registers and the states of these registers in each processing state, see section 30, List of Registers.

**Table 16.2 Register Configuration**

| Channel | Register Name                 | Abbreviation | R/W | Initial value | Address    | Access size |
|---------|-------------------------------|--------------|-----|---------------|------------|-------------|
| 0       | SS control register H_0       | SSCRH_0      | R/W | H'0D          | H'FFFE7000 | 8, 16       |
|         | SS control register L_0       | SSCRL_0      | R/W | H'00          | H'FFFE7001 | 8           |
|         | SS mode register_0            | SSMR_0       | R/W | H'00          | H'FFFE7002 | 8, 16       |
|         | SS enable register_0          | SSER_0       | R/W | H'00          | H'FFFE7003 | 8           |
|         | SS status register_0          | SSSR_0       | R/W | H'04          | H'FFFE7004 | 8, 16       |
|         | SS control register 2_0       | SSCR2_0      | R/W | H'00          | H'FFFE7005 | 8           |
|         | SS transmit data register 0_0 | SSTDR0_0     | R/W | H'00          | H'FFFE7006 | 8, 16       |
|         | SS transmit data register 1_0 | SSTDR1_0     | R/W | H'00          | H'FFFE7007 | 8           |
|         | SS transmit data register 2_0 | SSTDR2_0     | R/W | H'00          | H'FFFE7008 | 8, 16       |
|         | SS transmit data register 3_0 | SSTDR3_0     | R/W | H'00          | H'FFFE7009 | 8           |
|         | SS receive data register 0_0  | SSRDR0_0     | R   | H'00          | H'FFFE700A | 8, 16       |
|         | SS receive data register 1_0  | SSRDR1_0     | R   | H'00          | H'FFFE700B | 8           |
|         | SS receive data register 2_0  | SSRDR2_0     | R   | H'00          | H'FFFE700C | 8, 16       |
|         | SS receive data register 3_0  | SSRDR3_0     | R   | H'00          | H'FFFE700D | 8           |
| 1       | SS control register H_1       | SSCRH_1      | R/W | H'0D          | H'FFFE7800 | 8, 16       |
|         | SS control register L_1       | SSCRL_1      | R/W | H'00          | H'FFFE7801 | 8           |
|         | SS mode register_1            | SSMR_1       | R/W | H'00          | H'FFFE7802 | 8, 16       |
|         | SS enable register_1          | SSER_1       | R/W | H'00          | H'FFFE7803 | 8           |
|         | SS status register_1          | SSSR_1       | R/W | H'04          | H'FFFE7804 | 8, 16       |
|         | SS control register 2_1       | SSCR2_1      | R/W | H'00          | H'FFFE7805 | 8           |
|         | SS transmit data register 0_1 | SSTDR0_1     | R/W | H'00          | H'FFFE7806 | 8, 16       |
|         | SS transmit data register 1_1 | SSTDR1_1     | R/W | H'00          | H'FFFE7807 | 8           |
|         | SS transmit data register 2_1 | SSTDR2_1     | R/W | H'00          | H'FFFE7808 | 8, 16       |
|         | SS transmit data register 3_1 | SSTDR3_1     | R/W | H'00          | H'FFFE7809 | 8           |
|         | SS receive data register 0_1  | SSRDR0_1     | R   | H'00          | H'FFFE780A | 8, 16       |

| Channel | Register Name                | Abbreviation | R/W | Initial value | Address    | Access size |
|---------|------------------------------|--------------|-----|---------------|------------|-------------|
| 1       | SS receive data register 1_1 | SSRDR1_1     | R   | H'00          | H'FFFE780B | 8           |

|         | SS receive data register 3_1 | SSRDR3_1     | R   | H'00          | H'FFFE780D | 8           |

### 16.3.1 SS Control Register H (SSCRH)

SSCRH specifies master/slave device selection, bidirectional mode enable, SSO pin output value selection, SSCK pin selection, and SCS pin selection.

### 16.3.5 SS Status Register (SSSR)

SSSR is a status flag register for interrupts.

### 16.3.6 SS Control Register 2 (SSCR2)

SSCR2 is a register that selects the assert timing of the  $\overline{\text{SCS}}$  pin, data output timing of the SSO pin, and set timing of the TEND bit.

16.3.7 SS Transmit Data Registers 0 to 3 (SSTDR0 to SSTDR3)

SSTDR is an 8-bit register that stores transmit data. When 8-bit data length is selected by bits DATS1 and DATS0 in SSCRL, SSTDR0 is valid. When 16-bit data length is selected, SSTDR0 and SSTDR1 are valid. When 32-bit data length is selected, SSTDR0 to SSTDR3 are valid. The SSTDR that has not been enabled must not be accessed.

When the SSU detects that SSTRSR is empty, it transfers the transmit data written in SSTDR to SSTRSR and starts serial transmission. If the next transmit data has already been written to SSTDR during serial transmission, the SSU performs consecutive serial transmission.

Although SSTDR can always be read from or written to by the CPU and DMAC, to achieve reliable serial transmission, write transmit data to SSTDR after confirming that the TDRE bit in SSSR is set to 1.

| Bit    | Bit Name | Initial Value | R/W | Description          |
|--------|----------|---------------|-----|----------------------|
| 7 to 0 |          | All 0         | R/W | Serial transmit data |

Table 16.3 Correspondence between the DATS Bit Setting and SSTDR

| SSTDR | DATS[1:0] (SSCRL[1:0]) |         |       |                       |
|-------|------------------------|---------|-------|-----------------------|
|       | 00                     | 01      | 10    | 11 (Setting Disabled) |
| 0     | Valid                  | Valid   | Valid | Invalid               |
| 1     | Invalid                | Valid   | Valid | Invalid               |
| 2     | Invalid                | Invalid | Valid | Invalid               |
| 3     | Invalid                | Invalid | Valid | Invalid               |

### 16.3.8 SS Receive Data Registers 0 to 3 (SSRDR0 to SSRDR3)

SSRDR is an 8-bit register that stores receive data. When 8-bit data length is selected by bits DATS1 and DATS0 in SSCRL, SSRDR0 is valid. When 16-bit data length is selected, SSRDR0 and SSRDR1 are valid. When 32-bit data length is selected, SSRDR0 to SSRDR3 are valid. The SSRDR that has not been enabled must not be accessed.

When the SSU has received 1-byte data, it transfers the received serial data from SSTRSR to SSRDR where it is stored. After this, SSTRSR is ready for reception. Since SSTRSR and SSRDR function as a double buffer in this way, consecutive receive operations can be performed.

Read SSRDR after confirming that the RDRF bit in SSSR is set to 1.

SSRDR is a read-only register, therefore, cannot be written to by the CPU.

| 2     | Invalid                | Invalid | Valid | Invalid               |
| 3     | Invalid                | Invalid | Valid | Invalid               |

16.3.9 SS Shift Register (SSTRSR)

SSTRSR is a shift register that transmits and receives serial data.

When data is transferred from SSTDR to SSTRSR, bit 0 of transmit data is bit 0 in the SSTDR contents (MLS = 0: LSB first communication) and is bit 7 in the SSTDR contents (MLS = 1: MSB first communication). The SSU transfers data from the LSB (bit 0) in SSTRSR to the SSO pin to perform serial data transmission.

In reception, the SSU sets serial data that has been input via the SSI pin in SSTRSR from the LSB (bit 0). When 1-byte data has been received, the SSTRSR contents are automatically transferred to SSRDR. SSTRSR cannot be directly accessed by the CPU.

| Initial value: | - | - | - | - | - | - | - | - |
| R/W:           | - | - | - | - | - | - | - | - |

## 16.4 Operation

### 16.4.1 Transfer Clock

A transfer clock can be selected from among seven internal clocks and an external clock. Before using this module, enable the SSCK pin function in the PFC. When the MSS bit in SSCRH is 1, an internal clock is selected and the SSCK pin is used as an output pin. When transfer is started, the clock with the transfer rate set by bits CKS2 to CKS0 in SSMR is output from the SSCK pin. When MSS = 0, an external clock is selected and the SSCK pin is used as an input pin.

### 16.4.2 Relationship of Clock Phase, Polarity, and Data

The relationship of clock phase, polarity, and transfer data depends on the combination of the CPOS and CPHS bits in SSMR when the value of the SSUMS bit in SSCRL is 0. Figure 16.2 shows the relationship. When SSUMS = 1, the CPHS setting is invalid although the CPOS setting is valid. When SSUMS = 1, the transmit data change timing and receive data fetch timing are the same as that shown as “(1) When CPHS = 0” in figure 16.2.

Setting the MLS bit in SSMR selects either MSB first or LSB first communication. When MLS = 0, data is transferred from the LSB to the MSB. When MLS = 1, data is transferred from the MSB to the LSB.

**Figure 16.2 Relationship of Clock Phase, Polarity, and Data**

### 16.4.3 Relationship between Data Input/Output Pins and Shift Register

The connection between data input/output pins and the SS shift register (SSTRSR) depends on the combination of the MSS and BIDE bits in SSCRH and the SSUMS bit in SSCRL. Figure 16.3 shows the relationship.

The SSU transmits serial data from the SSO pin and receives serial data from the SSI pin when operating with BIDE = 0 and MSS = 1 (standard, master mode) (see figure 16.3 (1)). The SSU transmits serial data from the SSI pin and receives serial data from the SSO pin when operating with BIDE = 0 and MSS = 0 (standard, slave mode) (see figure 16.3 (2)).

The SSU transmits and receives serial data from the SSO pin regardless of master or slave mode when operating with BIDE = 1 (bidirectional mode) (see figures 16.3 (3) and (4)).

However, even if both the TE and RE bits are set to 1, transmission and reception are not performed simultaneously. Either the TE or RE bit must be selected.

The SSU transmits serial data from the SSO pin and receives serial data from the SSI pin when operating with SSUMS = 1. The SSCK pin outputs the internal clock when MSS = 1 and function as an input pin when MSS = 0 (see figures 16.3 (5) and (6)).

**Figure 16.3 Relationship between Data Input/Output Pins and the Shift Register**

### 16.4.4 Communication Modes and Pin Functions

The SSU switches the input/output pin (SSI, SSO, SSCK, and  $\overline{\text{SCS}}$ ) functions according to the communication modes and register settings. The relationship of communication modes and input/output pin functions are shown in tables 16.5 to 16.7.

**Table 16.5 Communication Modes and Pin States of SSI and SSO Pins**

| Communication Mode                     | Register Setting |      |     |    |    | Pin State |        |
|----------------------------------------|------------------|------|-----|----|----|-----------|--------|
|                                        | SSUMS            | BIDE | MSS | TE | RE | SSI       | SSO    |
| SSU communication mode                 | 0                | 0    | 0   | 0  | 1  | —         | Input  |
|                                        |                  |      |     | 1  | 0  | Output    | —      |
|                                        |                  |      |     |    | 1  | Output    | Input  |
|                                        |                  |      | 1   | 0  | 1  | Input     | —      |
|                                        |                  |      |     | 1  | 0  | —         | Output |
|                                        |                  |      |     |    | 1  | Input     | Output |
| SSU (bidirectional) communication mode | 0                | 1    | 0   | 0  | 1  | —         | Input  |
|                                        |                  |      |     | 1  | 0  | —         | Output |
|                                        |                  |      | 1   | 0  | 1  | —         | Input  |

### 16.4.5 SSU Mode

In SSU mode, data communications are performed via four lines: clock line (SSCK), data input line (SSI or SSO), data output line (SSI or SSO), and chip select line ( $\overline{\text{SCS}}$ ).

In addition, the SSU supports bidirectional mode in which a single pin functions as data input and data output lines.

#### (1) Initial Settings in SSU Mode

Figure 16.4 shows an example of the initial settings in SSU mode. Before data transfer, clear both the TE and RE bits in SSER to 0 to set the initial values.

**Note:** Before changing operating modes and communications formats, clear both the TE and RE bits to 0. Although clearing the TE bit to 0 sets the TDRE bit to 1, clearing the RE bit to 0 does not change the values of the RDRF and ORER bits and SSRDR. Those bits retain the previous values.

**Figure 16.4 Example of Initial Settings in SSU Mode**

## (2) Data Transmission

Figure 16.5 shows an example of transmission operation, and figure 16.6 shows a flowchart example of data transmission.

When transmitting data, the SSU operates as shown below.

In master mode, the SSU outputs a transfer clock and data. In slave mode, when a low level signal is input to the SCS pin and a transfer clock is input to the SSCK pin, the SSU outputs data in synchronization with the transfer clock.

Writing transmit data to SSTDR after the TE bit is set to 1 clears the TDRE bit in SSSR to 0, and the SSTDR contents are transferred to SSTRSR. After that, the SSU sets the TDRE bit to 1 and starts transmission. At this time, if the TIE bit in SSER is set to 1, a transmit-data-empty SSTXI interrupt is generated.

When 1-frame data has been transferred with TDRE = 0, the SSTDR contents are transferred to SSTRSR to start the next frame transmission. When the 8th bit of transmit data has been transferred with TDRE = 1, the TEND bit in SSSR is set to 1 and the state is retained. At this time, if the TEIE bit is set to 1, a transmit-end SSTXI interrupt is generated. After transmission, the output level of the SSCK pin is fixed high when CPOS = 0 and low when CPOS = 1.

While the ORER bit in SSSR is set to 1, transmission is not performed. Check that the ORER bit is cleared to 0 before transmission.

**Figure 16.5 Example of Transmission Operation (SSU Mode)**

**Figure 16.6 Flowchart Example of Data Transmission (SSU Mode)**

### (3) Data Reception

Figure 16.7 shows an example of reception operation, and figure 16.8 shows a flowchart example of data reception. When receiving data, the SSU operates as shown below.

After setting the RE bit to 1 and dummy-reading SSRDR, the SSU starts data reception.

In master mode, the SSU outputs a transfer clock and receives data. In slave mode, when a low level signal is input to the SCS pin and a transfer clock is input to the SSCK pin, the SSU receives data in synchronization with the transfer clock.

When 1-frame data has been received, the RDRF bit in SSSR is set to 1 and the receive data is stored in SSRDR. At this time, if the RIE bit in SSER is set to 1, an SSRXI interrupt is generated. The RDRF bit is automatically cleared to 0 by reading SSRDR.

During continuous slave reception in SSU mode, read the SS receive data register (SSRDR) before the next reception operation starts (before the externally connected master device starts the next transmission). When the next reception operation starts after the receive data full (RDRF) bit in the SS status register (SSSR) is set to 1 and before SSRDR is read, and SSRDR is read before reception of one frame completes, the conflict/incomplete error (CE) bit in SSSR is set to 1 after the reception operation ends. In addition, when the next reception operation starts after RDRF is set to 1 and before SSRDR is read, and SSRDR is not read before reception of one frame completes, the receive data is discarded, even though neither the CE bit nor the overrun error (ORER) bit in SSSR is set to 1.

(1) When 8-bit data length is selected (SSRDR0 is valid) with CPOS = 0 and CPHS = 0

(2) When 16-bit data length is selected (SSRDR0 and SSRDR1 are valid) with CPOS = 0 and CPHS = 0

(3) When 32-bit data length is selected (SSRDR0 to SSRDR3 are valid) with CPOS = 0 and CPHS = 0

**Figure 16.7 Example of Reception Operation (SSU Mode)**

**Figure 16.8 Flowchart Example of Data Reception (SSU Mode)**

#### (4) Data Transmission/Reception

Figure 16.9 shows a flowchart example of simultaneous transmission/reception. The data transmission/reception is performed combining the data transmission and data reception as mentioned above. The data transmission/reception is started by writing transmit data to SSTDR with  $TE = RE = 1$ . When the RDRF bit is set to 1, at the 8th rising edge of the transfer clock the ORER bit in SSSR is set to 1, an overrun error (SSERI) is generated, and both transmission and reception are stopped. Transmission and reception are not possible while the ORER bit is set to 1. To resume transmission and reception, clear the ORER bit to 0.

Before switching transmission mode ( $TE = 1$ ) or reception mode ( $RE = 1$ ) to transmission/reception mode ( $TE = RE = 1$ ), clear the TE and RE bits to 0. When starting the transfer, confirm that the TEND, RDRF, and ORER bits are cleared to 0 before setting the TE or RE bit to 1.

**Figure 16.9 Flowchart Example of Simultaneous Transmission/Reception (SSU Mode)**

### 16.4.6 $\overline{\text{SCS}}$ Pin Control and Conflict Error

When bits CSS1 and CSS0 in SSCRH are specified to B'10 and the SSUMS bit in SSCRL is cleared to 0, the  $\overline{\text{SCS}}$  pin functions as an input (Hi-Z) to detect a conflict error. A conflict error detection period is from setting the MSS bit in SSCRH to 1 to starting serial transfer and after transfer ends. When a low level signal is input to the  $\overline{\text{SCS}}$  pin within the period, a conflict error occurs. At this time, the CE bit in SSSR is set to 1 and the MSS bit is cleared to 0.

**Note:** While the CE bit is set to 1, transmission or reception is not resumed. Clear the CE bit to 0 before resuming the transmission or reception.

**Figure 16.10 Conflict Error Detection Timing (Before Transfer)**

**Figure 16.11 Conflict Error Detection Timing (After Transfer End)**

### 16.4.7 Clock Synchronous Communication Mode

In clock synchronous communication mode, data communications are performed via three lines: clock line (SSCK), data input line (SSI), and data output line (SSO).

#### (1) Initial Settings in Clock Synchronous Communication Mode

Figure 16.12 shows an example of the initial settings in clock synchronous communication mode. Before data transfer, clear both the TE and RE bits in SSER to 0 to set the initial values.

**Note:** Before changing operating modes and communications formats, clear both the TE and RE bits to 0. Although clearing the TE bit to 0 sets the TDRE bit to 1, clearing the RE bit to 0 does not change the values of the RDRF and ORER bits and SSRDR. Those bits retain the previous values.

**Figure 16.12 Example of Initial Settings in Clock Synchronous Communication Mode**

## (2) Data Transmission

Figure 16.13 shows an example of transmission operation, and figure 16.14 shows a flowchart example of data transmission. When transmitting data in clock synchronous communication mode, the SSU operates as shown below.

In master mode, the SSU outputs a transfer clock and data. In slave mode, when a transfer clock is input to the SSCK pin, the SSU outputs data in synchronization with the transfer clock.

Writing transmit data to SSTDR after the TE bit is set to 1 clears the TDRE bit in SSSR to 0, and the SSTDR contents are transferred to SSTRSR. After that, the SSU sets the TDRE bit to 1 and starts transmission. At this time, if the TIE bit in SSER is set to 1, a transmit-data-empty SSTXI interrupt is generated.

When 1-frame data has been transferred with TDRE = 0, the SSTDR contents are transferred to SSTRSR to start the next frame transmission. When the 8th bit of transmit data has been transferred with TDRE = 1, the TEND bit in SSSR is set to 1 and the state is retained. At this time, if the TEIE bit in SSER is set to 1, a transmit-end SSTXI interrupt is generated.

While the ORER bit in SSSR is set to 1, transmission is not performed. Check that the ORER bit is cleared to 0 before transmission.

**Figure 16.13 Example of Transmission Operation  
(Clock Synchronous Communication Mode)**

**Figure 16.14 Flowchart Example of Transmission Operation  
(Clock Synchronous Communication Mode)**

### (3) Data Reception

Figure 16.15 shows an example of reception operation, and figure 16.16 shows a flowchart example of data reception. When receiving data, the SSU operates as shown below.

After setting the RE bit in SSER to 1, the SSU starts data reception.

In master mode, the SSU outputs a transfer clock and receives data. In slave mode, when a transfer clock is input to the SSCK pin, the SSU receives data in synchronization with the transfer clock.

When 1-frame data has been received, the RDRF bit in SSSR is set to 1 and the receive data is stored in SSRDR. At this time, if the RIE bit is set to 1, an SSRXI interrupt is generated. The RDRF bit is automatically cleared to 0 by reading SSRDR.

When the RDRF bit has been set to 1 at the 8th rising edge of the transfer clock, the ORER bit in SSSR is set to 1. This indicates that an overrun error (SSERI) has occurred. At this time, data reception is stopped. While the ORER bit in SSSR is set to 1, reception is not performed. To resume the reception, clear the ORER bit to 0.

**Figure 16.15 Example of Reception Operation  
(Clock Synchronous Communication Mode)**

**Figure 16.16 Flowchart Example of Data Reception  
(Clock Synchronous Communication Mode)**

#### (4) Data Transmission/Reception

Figure 16.17 shows a flowchart example of simultaneous transmission/reception. The data transmission/reception is performed combining the data transmission and data reception as mentioned above. The data transmission/reception is started by writing transmit data to SSTDR with  $TE = RE = 1$ . When the RDRF bit is set to 1, at the 8th rising edge of the transfer clock the ORER bit in SSSR is set to 1, an overrun error (SSERI) is generated, and both transmission and reception are stopped. Transmission and reception are not possible while the ORER bit is set to 1. To resume transmission and reception, clear the ORER bit to 0.

Before switching transmission mode ( $TE = 1$ ) or reception mode ( $RE = 1$ ) to transmission/reception mode ( $TE = RE = 1$ ), clear the TE and RE bits to 0. When starting the transfer, confirm that the TEND, RDRF, and ORER bits are cleared to 0 before setting the TE or RE bits to 1.

**Figure 16.17 Flowchart Example of Simultaneous Transmission/Reception  
(Clock Synchronous Communication Mode)**

## 16.5 SSU Interrupt Sources and DMAC

The SSU interrupt requests are an overrun error, a conflict error, a receive data register full, transmit data register empty, and a transmit end interrupts. Of these interrupt sources, a receive data register full, and a transmit data register empty can activate the DMAC for data transfer.

Since both an overrun error and a conflict error interrupts are allocated to the SSERI vector address, and both a transmit data register empty and a transmit end interrupts are allocated to the SSTXI vector address, the interrupt source should be decided by their flags. Table 16.8 lists the interrupt sources.

When an interrupt condition shown in table 16.8 is satisfied, an interrupt is requested. Clear the interrupt source by CPU or DMAC data transfer.

**Table 16.8 SSU Interrupt Sources**

| Abbreviation | Interrupt Source             | Interrupt Condition                                                 | DMAC Activation |
|--------------|------------------------------|---------------------------------------------------------------------|-----------------|
| SSERI        | Overrun error                | $(RIE = 1) \bullet (ORER = 1) +$<br>$(CEIE = 1) \bullet (CE = 1)$   | —               |
|              | Conflict error               |                                                                     |                 |
| SSRXI        | Receive data register full   | $(RIE = 1) \bullet (RDRF = 1)$                                      | Possible        |
| SSTXI        | Transmit data register empty | $(TIE = 1) \bullet (TDRE = 1) +$<br>$(TEIE = 1) \bullet (TEND = 1)$ | Possible        |
|              | Transmit end                 |                                                                     |                 |

## 16.6 Usage Note

### 16.6.1 Module Standby Mode Setting

The SSU operation can be disabled or enabled using the standby control register. The initial setting is for SSU operation to be halted. Access to registers is enabled by clearing module standby mode. For details, refer to section 28, Power-Down Modes.

### 16.6.2 Note on Continuous Transmission/Reception in SSU Slave Mode

During continuous transmission or reception in SSU slave mode, negate (drive high level) the  $\overline{\text{SCS}}$  pin once per frame. Correct transmission and reception are not possible if the  $\overline{\text{SCS}}$  pin is asserted (low level) for more than one frame.

### 16.6.3 Note in the Master Transmission Operation or the Master Transmission/Reception Operation of SSU Mode

In the master transmission operation or the master transmission/reception operation of SSU mode, please operate one of the following three ways.

- (1) Write the next transmission data to the SSTDR after the TDRE bit of the SSSR is set to 1 and before the transmission of one bit before the last bit starts.
- (2) Write the next transmission data to the SSTDR after the TEND bit of the SSSR is set to 1.
- (3) Set the SSCR2 as “TENDSTS = 0” or “TENDSTS = 1 and SCSATS = 1”.

## Section 17 I<sup>2</sup>C Bus Interface 3 (IIC3)

The I<sup>2</sup>C bus interface 3 conforms to and provides a subset of the Philips I<sup>2</sup>C (Inter-IC) bus interface functions. However, the configuration of the registers that control the I<sup>2</sup>C bus differs partly from the Philips register configuration.

The I<sup>2</sup>C bus interface 3 has four channels.

### 17.1 Features

- Selection of I<sup>2</sup>C format or clocked synchronous serial format
- Continuous transmission/reception

Since the shift register, transmit data register, and receive data register are independent from each other, the continuous transmission/reception can be performed.

#### I<sup>2</sup>C bus format:

- Start and stop conditions generated automatically in master mode
- Selection of acknowledge output levels when receiving
- Automatic loading of acknowledge bit when transmitting
- Bit synchronization function

In master mode, the state of SCL is monitored per bit, and the timing is synchronized automatically. If transmission/reception is not yet possible, set the SCL to low until preparations are completed.

- Six interrupt sources  
Transmit data empty (including slave-address match), transmit end, receive data full (including slave-address match), arbitration lost, NACK detection, and stop condition detection
- The direct memory access controller (DMAC) can be activated by a transmit-data-empty request or receive-data-full request to transfer data.
- Direct bus drive  
Two pins, SCL and SDA pins, function as NMOS open-drain outputs when the bus drive function is selected.

#### Clocked synchronous serial format:

- Four interrupt sources  
Transmit-data-empty, transmit-end, receive-data-full, and overrun error
- The direct memory access controller (DMAC) can be activated by a transmit-data-empty request or receive-data-full request to transfer data.

Figure 17.1 shows a block diagram of the I<sup>2</sup>C bus interface 3.

**Figure 17.1 Block Diagram of I<sup>2</sup>C Bus Interface 3**

## 17.2 Input/Output Pins

Table 17.1 shows the pin configuration of the I<sup>2</sup>C bus interface 3.

**Table 17.1 Pin Configuration**

| Pin Name     | Symbol       | I/O | Function                                   |
|--------------|--------------|-----|--------------------------------------------|
| Serial clock | SCL0 to SCL3 | I/O | I <sup>2</sup> C serial clock input/output |
| Serial data  | SDA0 to SDA3 | I/O | I <sup>2</sup> C serial data input/output  |

Figure 17.2 shows an example of I/O pin connections to external circuits.

**Figure 17.2 External Circuit Connections of I/O Pins**

## 17.3 Register Descriptions

The I<sup>2</sup>C bus interface 3 has the following registers.

**Table 17.2 Register Configuration**

| Channel | Register Name                                  | Abbreviation | R/W | Initial Value | Address    | Access Size |
|---------|------------------------------------------------|--------------|-----|---------------|------------|-------------|
| 0       | I <sup>2</sup> C bus control register 1        | ICCR1_0      | R/W | H'00          | H'FFFEE000 | 8           |
|         | I <sup>2</sup> C bus control register 2        | ICCR2_0      | R/W | H'7D          | H'FFFEE001 | 8           |
|         | I <sup>2</sup> C bus mode register             | ICMR_0       | R/W | H'38          | H'FFFEE002 | 8           |
|         | I <sup>2</sup> C bus interrupt enable register | ICIER_0      | R/W | H'00          | H'FFFEE003 | 8           |
|         | I <sup>2</sup> C bus status register           | ICSR_0       | R/W | H'00          | H'FFFEE004 | 8           |
|         | Slave address register                         | SAR_0        | R/W | H'00          | H'FFFEE005 | 8           |
|         | I <sup>2</sup> C bus transmit data register    | ICDRT_0      | R/W | H'FF          | H'FFFEE006 | 8           |
|         | I <sup>2</sup> C bus receive data register     | ICDRR_0      | R/W | H'FF          | H'FFFEE007 | 8           |
|         | NF2CYC register                                | NF2CYC_0     | R/W | H'00          | H'FFFEE008 | 8           |
| 1       | I <sup>2</sup> C bus control register 1        | ICCR1_1      | R/W | H'00          | H'FFFEE400 | 8           |
|         | I <sup>2</sup> C bus control register 2        | ICCR2_1      | R/W | H'7D          | H'FFFEE401 | 8           |
|         | I <sup>2</sup> C bus mode register             | ICMR_1       | R/W | H'38          | H'FFFEE402 | 8           |
|         | I <sup>2</sup> C bus interrupt enable register | ICIER_1      | R/W | H'00          | H'FFFEE403 | 8           |
|         | I <sup>2</sup> C bus status register           | ICSR_1       | R/W | H'00          | H'FFFEE404 | 8           |
|         | Slave address register                         | SAR_1        | R/W | H'00          | H'FFFEE405 | 8           |
|         | I <sup>2</sup> C bus transmit data register    | ICDRT_1      | R/W | H'FF          | H'FFFEE406 | 8           |

### 17.3.1 I<sup>2</sup>C Bus Control Register 1 (ICCR1)

ICCR1 is an 8-bit readable/writable register that enables or disables the I<sup>2</sup>C bus interface 3, controls transmission or reception, and selects master or slave mode, transmission or reception, and transfer clock frequency in master mode.

ICCR1 is initialized to H'00 by a power-on reset.

|                |     |      |     |     |          |     |     |     |

Note: The settings should satisfy external specifications.

### 17.3.2 I<sup>2</sup>C Bus Control Register 2 (ICCR2)

ICCR2 is an 8-bit readable/writable register that issues start/stop conditions, manipulates the SDA pin, monitors the SCL pin, and controls reset in the control part of the I<sup>2</sup>C bus.

|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | BBSY     | 0             | R/W | <b>Bus Busy</b><br>Enables to confirm whether the I <sup>2</sup> C bus is occupied or released and to issue start/stop conditions in master mode. With the clocked synchronous serial format, this bit is always read as 0. With the I <sup>2</sup> C bus format, this bit is set to 1 when the SDA level changes from high to low under the condition of SCL = high, assuming that the start condition has been issued. This bit is cleared to 0 when the SDA level changes from low to high under the condition of SCL = high, assuming that the stop condition has been issued. Write 1 to BBSY and 0 to SCP to issue a start condition. Follow this procedure when also re-transmitting a start condition. Write 0 in BBSY and 0 in SCP to issue a stop condition. |
| 6   | SCP      | 1             | R/W | <b>Start/Stop Issue Condition Disable</b><br>Controls the issue of start/stop conditions in master mode. To issue a start condition, write 1 in BBSY and 0 in SCP. A retransmit start condition is issued in the same way. To issue a stop condition, write 0 in BBSY and 0 in SCP. This bit is always read as 1. Even if 1 is written to this bit, the data will not be stored.                                                                                                                                                                                                                                                                                                                                                                                       |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                  |

### 17.3.3 I<sup>2</sup>C Bus Mode Register (ICMR)

ICMR is an 8-bit readable/writable register that selects whether the MSB or LSB is transferred first, performs master mode wait control, and selects the transfer bit count.

Bits BC[2:0] are initialized to H'0 by the IICRST bit in ICCR2.
